## DOCUMENTATION CONTENTS

## 1.1 Shapely

Manipulation and analysis of geometric objects in the Cartesian plane.

Shapely is a BSD-licensed Python package for manipulation and analysis of planar geometric objects. It is based on the widely deployed [GEOS](#) (the engine of [PostGIS](#)) and [JTS](#) (from which GEOS is ported) libraries. Shapely is not concerned with data formats or coordinate systems, but can be readily integrated with packages that are. For more details, see:

- [Shapely GitHub repository](#)
- [Shapely documentation and manual](#)

### 1.1.1 Usage

Here is the canonical example of building an approximately circular patch by buffering a point.

```
>>> from shapely.geometry import Point
>>> patch = Point(0.0, 0.0).buffer(10.0)
>>> patch
<shapely.geometry.polygon.Polygon object at 0x...>
>>> patch.area
313.65484905459385
```

See the manual for more examples and guidance.

### 1.1.2 Requirements

Shapely 1.8 requires

- Python >=3.6
- GEOS >=3.3

### 1.1.3 Installing Shapely

Shapely may be installed from a source distribution or one of several kinds of built distribution.

#### Built distributions

Built distributions are the only option for users who do not have or do not know how to use their platform's compiler and Python SDK, and a good option for users who would rather not bother.

Linux, OS X, and Windows users can get Shapely wheels with GEOS included from the Python Package Index with a recent version of pip (8+):

```
$ pip install shapely
```

Shapely is available via system package management tools like apt, yum, and Homebrew, and is also provided by popular Python distributions like Canopy and Anaconda. If you use the Conda package manager to install Shapely, be sure to use the conda-forge channel.

Windows users have another good installation options: the wheels published at <https://www.lfd.uci.edu/~gohlke/pythonlibs/#shapely>. These can be installed using pip by specifying the entire URL.

#### Source distributions

If you want to build Shapely from source for compatibility with other modules that depend on GEOS (such as cartopy or osgeo.ogr) or want to use a different version of GEOS than the one included in the project wheels you should first install the GEOS library, Cython, and Numpy on your system (using apt, yum, brew, or other means) and then direct pip to ignore the binary wheels.

```
$ pip install shapely --no-binary shapely
```

If you've installed GEOS to a standard location, the geos-config program will be used to get compiler and linker options. If geos-config is not on your executable, it can be specified with a GEOS\_CONFIG environment variable, e.g.:

```
$ GEOS_CONFIG=/path/to/geos-config pip install shapely
```

### 1.1.4 Integration

Shapely does not read or write data files, but it can serialize and deserialize using several well known formats and protocols. The `shapely.wkb` and `shapely.wkt` modules provide dumpers and loaders inspired by Python's `pickle` module.

```
>>> from shapely.wkt import dumps, loads
>>> dumps(loads('POINT (0 0)'))
'POINT (0.0000000000000000 0.0000000000000000)'
```

Shapely can also integrate with other Python GIS packages using GeoJSON-like dicts.

```
>>> import json
>>> from shapely.geometry import mapping, shape
>>> s = shape(json.loads('{"type": "Point", "coordinates": [0.0, 0.0]}'))
>>> s
<shapely.geometry.point.Point object at 0x...>
>>> print(json.dumps(mapping(s)))
{"type": "Point", "coordinates": [0.0, 0.0]}
```

### 1.1.5 Development and Testing

Dependencies for developing Shapely are listed in `requirements-dev.txt`. Cython and Numpy are not required for production installations, only for development. Use of a virtual environment is strongly recommended.

```
$ virtualenv .
$ source bin/activate
(env)$ pip install -r requirements-dev.txt
(env)$ pip install -e .
```

The project uses `pytest` to run Shapely's suite of unittests and doctests.

```
(env)$ python -m pytest
```

### 1.1.6 Support

Questions about using Shapely may be asked on the [GIS StackExchange](https://gis.stackexchange.com/) using the “shapely” tag.

Bugs may be reported at <https://github.com/Toblerity/Shapely/issues>.

### 1.1.7 Credits

Shapely is written by:

Additional help from:

- Justin Bronn (GeoDjango) for ctypes inspiration
- Martin Davis (JTS)
- Sandro Santilli, Mateusz Loskot, Paul Ramsey, et al (GEOS Project)

Major portions of this work were supported by a grant (for [Pleiades](https://www.neh.gov)) from the U.S. National Endowment for the Humanities (<https://www.neh.gov>).

## 1.1.8 Changes

### 1.8.0 (2021-10-25)

This is the final 1.8.0 release. There have been no changes since 1.8rc2.

### 1.8rc2 (2021-10-19)

Build:

A pyproject.toml file has been added to specify build dependencies for the `_vectorized` and `_speedups` modules (#1128). To install shapely without these build dependencies, use the features of your build tool that disable PEP 517 and 518 support.

Bug fixes:

- Part of PR #1042, which added a new primary GEOS library name to be searched for, has been reverted by PR #1201.

### 1.8rc1 (2021-10-04)

#### Deprecations:

The `almost_exact()` method of `BaseGeometry` has been deprecated. It is confusing and will be removed in 2.0.0. The `equals_exact()` method is to be used instead.

#### Bug fixes:

- We ensure that the `_speedups` module is always imported before `_vectorized` to avoid an unexplained condition on Windows with Python 3.8 and 3.9 (#1184).

### 1.8a3 (2021-08-24)

#### Deprecations:

The `STRtree` class deprecation warnings have been removed. The class in 2.0.0 will be backwards compatible with the class in 1.8.0.

#### Bug fixes:

- The `__array_interface__` raises only `AttributeError`, all other exceptions are deprecated starting with Numpy 1.21 (#1173).
- The `STRtree` class now uses a pair of item, geom sequences internally instead of a dict (#1177).

### 1.8a2 (2021-07-15)

#### Python version support:

Shapely 1.8 will support only Python versions  $\geq 3.6$ .

#### New features:

- The `STRtree` `nearest*`() methods now take an optional argument that specifies exclusion of the input geometry from results (#1115).
- A `GeometryTypeError` has been added to `shapely.errors` and is consistently raised instead of `TypeError` or `ValueError` as in version 1.7. For backwards compatibility, the new exception will derive from `TypeError` and `ValueError` until version 2.0 (#1099).
- The `STRtree` class constructor now takes an optional second argument, a sequence of objects to be stored in the tree. If not provided, the sequence indices of the geometries will be stored, as before (#1112).
- The `STRtree` class has new `query_geoms()`, `query_items()`, `nearest_geom()`, and `nearest_item()` methods (#1112). The `query()` and `nearest()` methods remain as aliases for `query_geoms()` and `nearest_geom()`.

#### Bug fixes:

- We no longer attempt to load `libc` to get the `free` function on Linux, but get it from the global symbol table.
- GEOS error messages printed when `GEOS_getCoordSeq()` is passed an empty geometry are avoided by never passing an empty geometry (#1134).
- Python's builtin `super()` is now used only as described in PEP 3135 (#1109).
- Only load conda GEOS dll if it exists (on Windows) (#1108).
- Add `/opt/homebrew/lib` to the list of directories to be searched for the GEOS shared library.
- Added new library search path to assist app creation with `cx_Freeze`.

## 1.8a1 (2021-03-03)

Shapely 1.8.0 will be a transitional version. There are a few bug fixes and new features, but it is mainly about warning of the upcoming changes in 2.0.0. Several more pre-releases before 1.8.0 are expected. See the migration guide to Shapely 1.8 / 2.0 for more details on how to update your code (<https://shapely.readthedocs.io/en/latest/migration.html>).

Python version support:

Shapely 1.8 will support only Python versions  $\geq 3.5$  (#884).

Deprecations:

The following functions and geometry attributes and methods will be removed in version 2.0.0.

- `ops.cascaded_union`
- `geometry.empty()`
- `geometry.ctypes` and `__array_interface__`
- multi-part geometry `__len__`
- setting custom attributes on geometry objects

Geometry objects will become immutable in version 2.0.0.

The `STRtree` class will be entirely changed in 2.0.0. The exact future API is not yet decided, but will be decided before 1.8.0 is released.

Deprecation warnings will be emitted in 1.8a1 when any of these features are used.

The deprecated `.to_wkb()` and `.to_wkt()` methods on the geometry objects have been removed.

New features:

- Add a `normalize()` method to geometry classes, exposing the `GEOSNormalize` algorithm (#1090).
- Initialize `STRtree` with a capacity of 10 items per node (#1070).
- Load libraries relocated to `shapely/.libs` by auditwheel versions  $< 3.1$  or relocated to `Shapely.libs` by auditwheel versions  $\geq 3.1$ .
- `shapely.ops.voronoi_diagram()` computes the Voronoi Diagram of a geometry or geometry collection (#833, #851).
- `shapely.validation.make_valid()` fixes invalid geometries (#883)

Bug fixes:

- For `pyinstaller` we now handle the case of more than one `GEOS` library in the environment, such as when `fiona` and `rasterio` wheels are co-installed with `shapely` (#1071).
- The `ops.split` function now splits on touch to eliminate confusing discrepancies between results using multi and single part splitters (#1034).
- Several issues with duplication and order of vertices in `ops.substring` have been fixed (#1008).

Packaging:

- The wheels uploaded to PyPI will include `GEOS 3.9.1`.

### 1.7.1 (2020-08-20)

- STRtree now safely implements the pickle protocol (#915).
- Documentation has been added for `minimum_clearance` (#875, #874).
- In `STRtree.__del__()` we guard against calling `GEOSSTRtree_destroy` when the `lgeos` module has already been torn down on exit (#897, #830).
- Documentation for the `overlaps()` method has been corrected (#920).
- Correct the test in `shapely.geometry.base.BaseGeometry.empty()` to eliminate memory leaks like the one reported in #745.
- Get `free()` not from `libc` but from the processes global symbols (#891), fixing a bug that manifests on OS X 10.15 and 10.16.
- Extracting substrings from complex lines has been made more correct (#848, #849).
- Splitting of complex geometries has been sped up by preparing the input geometry (#871).
- Fix bug in concatenation of function argtypes (#866).
- Improved documentation of STRtree usage (#857).
- Improved handling for empty list or list of lists in GeoJSON coordinates (#852).
- The polylabel algorithm now accounts for polygon holes (#851, #817).

### 1.7.0 (2020-01-28)

This is the final 1.7.0 release. There have been no changes since 1.7b1.

### 1.7b1 (2020-01-13)

First beta release.

### 1.7a3 (2019-12-31)

New features:

- The buffer operation can now be single-sides (#806, #727).

Bug fixes:

- Add `/usr/local/lib` to the list of directories to be searched for the GEOS shared library (#795).
- `ops.substring` now returns a line with coords in end-to-front order when given a start position that is greater than the end position (#628).
- Implement `__bool__()` for geometry base classes so that `bool(geom)` returns the logical complement of `geom.is_empty` (#754).
- Remove assertion on the number of version-like strings found in the GEOS version string. It could be 2 or 3.

### 1.7a2 (2019-06-21)

- Nearest neighbor search has been added to STRtree (#668).
- Disallow sequences of MultiPolygons as arguments to the MultiPolygon constructor, resolving #588.
- Removed vendorized *functools* functions previously used to support Python 2.5.

#### Bug fixes:

- Avoid reloading the GEOS shared library when using an installed binary wheel on OS X (#735), resolving issue #553.
- The `shapely.ops.orient` function can now orient multi polygons and geometry collections as well as polygons (#733).
- Polygons can now be constructed from sequences of point objects as well as sequences of x, y sequences (#732).
- The exterior of an empty polygon is now equal to an empty linear ring (#731).
- The bounds property of an empty point object now returns an empty tuple, consistent with other geometry types (#723).
- Segmentation faults when non-string values are passed to the WKT loader are avoided by #700.
- Failure of `ops.substring` when the sub linestring coincides with the beginning of the linestring has been fixed (#658).
- Segmentation faults from interpolating on an empty linestring are prevented by #655.
- A missing special case for rectangular polygons has been added to the polylabel algorithm (#644).
- LinearRing can be created from a LineString (#638).
- The prepared geometry validation condition has been tightened in #632 to fix the bug reported in #631.
- Attempting to interpolate an empty geometry no longer results in a segmentation fault, raising *ValueError* instead (#653).

### 1.7a1 (2018-07-29)

#### New features:

- A Python version check is made by the package setup script. Shapely 1.7 supports only Python versions 2.7 and 3.4+ (#610).
- Added a new *EmptyGeometry* class to support GeoPandas (#514).
- Added new `shapely.ops.substring` function (#459).
- Added new `shapely.ops.clip_by_rect` function (#583).
- Use DLLs indicated in `sys._MEIPASS` to support PyInstaller frozen apps (#523).
- `shapely.wkb.dumps` now accepts an *srid* integer keyword argument to write WKB data including a spatial reference ID in the output data (#593).

#### Bug fixes:

- `shapely.geometry.shape` can now marshal empty GeoJSON representations (#573).
- An exception is raised when an attempt is made to *prepare* a *PreparedGeometry* (#577, #595).
- Keyword arguments have been removed from a geometry object's *wkt* property getter (#581, #594).

### 1.6.4.post1 (2018-01-24)

- Fix broken markup in this change log, which restores our nicely formatted readme on PyPI.

### 1.6.4 (2018-01-24)

- Handle a `TypeError` that can occur when geometries are torn down (#473, #528).

### 1.6.3 (2017-12-09)

- `AttributeError` is no longer raised when accessing `__geo_interface__` of an empty polygon (#450).
- `asShape` now handles empty coordinates in mappings as `shape` does (#542). Please note that `asShape` is likely to be deprecated in a future version of Shapely.
- Check for length of `LineString` coordinates in speed mode, preventing crashes when using `LineStrings` with only one coordinate (#546).

### 1.6.2 (2017-10-30)

- A 1.6.2.post1 release has been made to fix a problem with macosx wheels uploaded to PyPI.

### 1.6.2 (2017-10-26)

- Splitting a `linestring` by one of its end points will now succeed instead of failing with a `ValueError` (#524, #533).
- Missing documentation of a geometry's `overlaps` predicate has been added (#522).

### 1.6.1 (2017-09-01)

- Avoid `STRTree` crashes due to dangling references (#505) by maintaining references to added geometries.
- Reduce log level to debug when reporting on calls to `ctypes.CDLL()` that don't succeed and are retried (#515).
- Clarification: applications like `GeoPandas` that need an empty geometry object should use `BaseGeometry()` instead of `Point()` or `Polygon()`. An `EmptyGeometry` class has been added in the master development branch and will be available in the next non-bugfix release.

### 1.6.0 (2017-08-21)

Shapely 1.6.0 adds new attributes to existing geometry classes and new functions (`split()` and `polylabel()`) to the `shapely.ops` module. Exceptions are consolidated in a `shapely.errors` module and logging practices have been improved. Shapely's optional features depending on Numpy are now gathered into a requirements set named "vectorized" and these may be installed like `pip install shapely[vectorized]`.

Much of the work on 1.6.0 was aimed to improve the project's build and packaging scripts and to minimize run-time dependencies. Shapely now vendorizes packaging to use during builds only and never again invokes the `geos-config` utility at run-time.

In addition to the changes listed under the alpha and beta pre-releases below, the following change has been made to the project:

- Project documentation is now hosted at <https://shapely.readthedocs.io/en/latest/>.

Thank you all for using, promoting, and contributing to the Shapely project.

### **1.6b5 (2017-08-18)**

Bug fixes:

- Passing a single coordinate to `LineString()` with speedups disabled now raises a `ValueError` as happens with speedups enabled. This resolves #509.

### **1.6b4 (2017-02-15)**

Bug fixes:

- Isolate vendorized packaging in a `_vendor` directory, remove obsolete dist-info, and remove packaging from project requirements (resolves #468).

### **1.6b3 (2016-12-31)**

Bug fixes:

- Level for log messages originating from the GEOS notice handler reduced from `WARNING` to `INFO` (#447).
- Permit speedups to be imported again without Numpy (#444).

### **1.6b2 (2016-12-12)**

New features:

- Add support for `GeometryCollection` to `shape` and `asShape` functions (#422).

### **1.6b1 (2016-12-12)**

Bug fixes:

- Implemented `__array_interface__` for empty `Points` and `LineStrings` (#403).

### **1.6a3 (2016-12-01)**

Bug fixes:

- Remove accidental hard requirement of Numpy (#431).

Packaging:

- Put Numpy in an optional requirement set named “vectorized” (#431).

### 1.6a2 (2016-11-09)

Bug fixes:

- Shapely no longer configures logging in `geos.py` (#415).

Refactoring:

- Consolidation of exceptions in `shapely.errors`.
- `UnsupportedGEOSVersionError` is raised when `GEOS < 3.3.0` (#407).

Packaging:

- Added new library search paths to assist Anaconda (#413).
- `geos-config` will now be bypassed when `NO_GEOS_CONFIG` env var is set. This allows configuration of Shapely builds on Linux systems that for whatever reasons do not include the `geos-config` program (#322).

### 1.6a1 (2016-09-14)

New features:

- A new error derived from `NotImplementedError`, with a more useful message, is raised when the GEOS backend doesn't support a called method (#216).
- The `project()` method of `LineString` has been extended to `LinearRing` geometries (#286).
- A new `minimum_rotated_rectangle` attribute has been added to the base geometry class (#354).
- A new `shapely.ops.polylabel()` function has been added. It computes a point suited for labeling concave polygons (#395).
- A new `shapely.ops.split()` function has been added. It splits a geometry by another geometry of lesser dimension: polygon by line, line by point (#293, #371).
- `Polygon.from_bounds()` constructs a `Polygon` from bounding coordinates (#392).
- Support for testing with Numpy 1.4.1 has been added (#301).
- Support creating all kinds of empty geometries from empty lists of Python objects (#397, #404).

Refactoring:

- Switch from `SingleSidedBuffer()` to `OffsetCurve()` for `GEOS >= 3.3` (#270).
- Cython speedups are now enabled by default (#252).

Packaging:

- Packaging 16.7, a setup dependency, is vendored (#314).
- Infrastructure for building manylinux1 wheels has been added (#391).
- The system's `geos-config` program is now only checked when `setup.py` is executed, never during normal use of the module (#244).
- Added new library search paths to assist PyInstaller (#382) and Windows (#343).

### 1.5.17 (2016-08-31)

- Bug fix: eliminate memory leak in `geom_factory()` (#408).
- Bug fix: remove mention of negative distances in `parallel_offset` and note that vertices of right hand offset lines are reversed (#284).

### 1.5.16 (2016-05-26)

- Bug fix: eliminate memory leak when unpickling geometry objects (#384, #385).
- Bug fix: prevent crashes when attempting to pickle a prepared geometry, raising `PicklingError` instead (#386).
- Packaging: extension modules in the OS X wheels uploaded to PyPI link only `libgeos_c.dylib` now (you can verify and compare to previous releases with `otool -L shapely/vectorized/_vectorized.so`).

### 1.5.15 (2016-03-29)

- Bug fix: use `uintptr_t` to store pointers instead of `long` in `_geos.pxi`, preventing an overflow error (#372, #373). Note that this bug fix was erroneously reported to have been made in 1.5.14, but was not.

### 1.5.14 (2016-03-27)

- Bug fix: use `type()` instead of `isinstance()` when evaluating geometry equality, preventing instances of base and derived classes from being mistaken for equals (#317).
- Bug fix: ensure that empty geometries are created when constructors have no args (#332, #333).
- Bug fix: support app “freezing” better on Windows by not relying on the `__file__` attribute (#342, #377).
- Bug fix: ensure that empty polygons evaluate to be `==` (#355).
- Bug fix: filter out empty geometries that can cause segfaults when creating and loading STRtrees (#345, #348).
- Bug fix: no longer attempt to reuse GEOS DLLs already loaded by Rasterio or Fiona on OS X (#374, #375).

### 1.5.13 (2015-10-09)

- Restore setup and runtime discovery and loading of GEOS shared library to state at version 1.5.9 (#326).
- On OS X we try to reuse any GEOS shared library that may have been loaded via import of Fiona or Rasterio in order to avoid a bug involving the GEOS `AbstractSTRtree` (#324, #327).

### 1.5.12 (2015-08-27)

- Remove configuration of root logger from `libgeos.py` (#312).
- Skip `test_fallbacks` on Windows (#308).
- Call `setlocale(locale.LC_ALL, “”)` instead of `resetlocale()` on Windows when tearing down the locale test (#308).
- Fix for Sphinx warnings (#309).
- Addition of `.cache`, `.idea`, `.pyd`, `.pdb` to `.gitignore` (#310).

### 1.5.11 (2015-08-23)

- Remove packaging module requirement added in 1.5.10 (#305). Distutils can't parse versions using 'rc', but if we stick to 'a' and 'b' we will be fine.

### 1.5.10 (2015-08-22)

- Monkey patch affinity module by absolute reference (#299).
- Raise TopologicalError in relate() instead of crashing (#294, #295, #303).

### 1.5.9 (2015-05-27)

- Fix for 64 bit speedups compatibility (#274).

### 1.5.8 (2015-04-29)

- Setup file encoding bug fix (#254).
- Support for pyinstaller (#261).
- Major prepared geometry operation fix for Windows (#268, #269).
- Major fix for OS X binary wheel (#262).

### 1.5.7 (2015-03-16)

- Test and fix buggy error and notice handlers (#249).

### 1.5.6 (2015-02-02)

- Fix setup regression (#232, #234).
- SVG representation improvements (#233, #237).

### 1.5.5 (2015-01-20)

- MANIFEST changes to restore \_geox.pxi (#231).

### 1.5.4 (2015-01-19)

- Fixed OS X binary wheel library load path (#224).

### 1.5.3 (2015-01-12)

- Fixed ownership and potential memory leak in polygonize (#223).
- Wider release of binary wheels for OS X.

### 1.5.2 (2015-01-04)

- Fail installation if GEOS dependency is not met, preventing update breakage (#218, #219).

### 1.5.1 (2014-12-04)

- Restore geometry hashing (#209).

### 1.5.0 (2014-12-02)

- Affine transformation speedups (#197).
- New `==` rich comparison (#195).
- Geometry collection constructor (#200).
- `ops.snap()` backed by `GEOSSnap` (#201).
- Clearer exceptions in cases of topological invalidity (#203).

### 1.4.4 (2014-11-02)

- Proper conversion of numpy float32 vals to coords (#186).

### 1.4.3 (2014-10-01)

- Fix for endianness bug in WKB writer (#174).

### 1.4.2 (2014-09-29)

- Fix bungled 1.4.1 release (#176).

### 1.4.1 (2014-09-23)

- Return of support for GEOS 3.2 (#176, #178).

### 1.4.0 (2014-09-08)

- SVG representations for IPython's inline image protocol.
- Efficient and fast vectorized contains().
- Change mitre\_limit default to 5.0; raise ValueError with 0.0 (#139).
- Allow mix of tuples and Points in sped-up LineString ctor (#152).
- New STRtree class (#73).
- Add ops.nearest\_points() (#147).
- Faster creation of geometric objects from others (cloning) (#165).
- Removal of tests from package.

### 1.3.3 (2014-07-23)

- Allow single-part geometries as argument to ops.cacaded\_union() (#135).
- Support affine transformations of LinearRings (#112).

### 1.3.2 (2014-05-13)

- Let LineString() take a sequence of Points (#130).

### 1.3.1 (2014-04-22)

- More reliable proxy cleanup on exit (#106).
- More robust DLL loading on all platforms (#114).

### 1.3.0 (2013-12-31)

- Include support for Python 3.2 and 3.3 (#56), minimum version is now 2.6.
- Switch to GEOS WKT/WKB Reader/Writer API, with defaults changed to enable 3D output dimensions, and to 'trim' WKT output for GEOS >=3.3.0.
- Use GEOS version instead of GEOS C API version to determine library capabilities (#65).

### 1.2.19 (2013-12-30)

- Add buffering style options (#55).

### 1.2.18 (2013-07-23)

- Add `shapely.ops.transform`.
- Permit empty sequences in collection constructors (#49, #50).
- Individual polygons in `MultiPolygon.__geo_interface__` are changed to tuples to match `Polygon.__geo_interface__` (#51).
- Add `shapely.ops.polygonize_full` (#57).

### 1.2.17 (2013-01-27)

- Avoid circular import between `wkt/wkb` and `geometry.base` by moving calls to GEOS serializers to the latter module.
- Set `_ndim` when unpickling (issue #6).
- Don't install DLLs to Python's DLL directory (#37).
- Add affinity module of affine transformation (#31).
- Fix `NameError` that blocked installation with PyPy (#40, #41).

### 1.2.16 (2012-09-18)

- Add `ops.unary_union` function.
- Alias `ops.cascaded_union` to `ops.unary_union` when GEOS CAPI  $\geq (1,7,0)$ .
- Add `geos_version_string` attribute to `shapely.geos`.
- Ensure parent is set when child geometry is accessed.
- Generate `_speedups.c` using Cython when building from repo when missing, stale, or the build target is "sdist".
- The `is_simple` predicate of invalid, self-intersecting linear rings now returns `False`.
- Remove `VERSION.txt` from repo, it's now written by the `distutils` setup script with value of `shapely.__version__`.

### 1.2.15 (2012-06-27)

- Eliminate numerical sensitivity in a method chaining test (Debian bug #663210).
- Account for cascaded union of random buffered test points being a polygon or multipolygon (Debian bug #666655).
- Use Cython to build speedups if it is installed.
- Avoid stumbling over SVN revision numbers in GEOS C API version strings.

#### 1.2.14 (2012-01-23)

- A geometry's `coords` property is now sliceable, yielding a list of coordinate values.
- Homogeneous collections are now sliceable, yielding a new collection of the same type.

#### 1.2.13 (2011-09-16)

- Fixed errors in speedups on 32bit systems when GEOS references memory above 2GB.
- Add `shapely.__version__` attribute.
- Update the manual.

#### 1.2.12 (2011-08-15)

- Build Windows distributions with VC7 or VC9 as appropriate.
- More verbose report on failure to speed up.
- Fix for prepared geometries broken in 1.2.11.
- DO NOT INSTALL 1.2.11

#### 1.2.11 (2011-08-04)

- Ignore `AttributeError` during exit.
- PyPy 1.5 support.
- Prevent operation on prepared geometry crasher (#12).
- Optional Cython speedups for Windows.
- Linux 3 platform support.

#### 1.2.10 (2011-05-09)

- Add optional Cython speedups.
- Add `is_cww` predicate to `LinearRing`.
- Add function that forces orientation of `Polygons`.
- Disable build of speedups on Windows pending packaging work.

#### 1.2.9 (2011-03-31)

- Remove extra `glob` import.
- Move examples to `shapely.examples`.
- Add `box()` constructor for rectangular polygons.
- Fix extraneous imports.

### 1.2.8 (2011-12-03)

- New `parallel_offset` method (#6).
- Support for Python 2.4.

### 1.2.7 (2010-11-05)

- Support for Windows eggs.

### 1.2.6 (2010-10-21)

- The `geoms` property of an empty collection yields `[]` instead of a `ValueError` (#3).
- The `coords` and `geometry` type `sproperties` have the same behavior as above.
- Ensure that `z` values carry through into products of operations (#4).

### 1.2.5 (2010-09-19)

- Stop distributing `docs/_build`.
- Include library fallbacks in `test_dlls.py` for linux platform.

### 1.2.4 (2010-09-09)

- Raise `AttributeError` when there's no backend support for a method.
- Raise `OSError` if `libgeos_c.so` (or variants) can't be found and loaded.
- Add `geos_c` DLL loading support for linux platforms where `find_library` doesn't work.

### 1.2.3 (2010-08-17)

- Add mapping function.
- Fix problem with `GEOSisValidReason` symbol for `GEOS < 3.1`.

### 1.2.2 (2010-07-23)

- Add `representative_point` method.

### 1.2.1 (2010-06-23)

- Fixed bounds of singular polygons.
- Added `shapely.validation.explain_validity` function (#226).

## **1.2 (2010-05-27)**

- Final release.

## **1.2rc2 (2010-05-26)**

- Add examples and tests to MANIFEST.in.
- Release candidate 2.

## **1.2rc1 (2010-05-25)**

- Release candidate.

## **1.2b7 (2010-04-22)**

- Memory leak associated with new empty geometry state fixed.

## **1.2b6 (2010-04-13)**

- Broken GeometryCollection fixed.

## **1.2b5 (2010-04-09)**

- Objects can be constructed from others of the same type, thereby making copies. Collections can be constructed from sequences of objects, also making copies.
- Collections are now iterators over their component objects.
- New code for manual figures, using the descartes package.

## **1.2b4 (2010-03-19)**

- Adds support for the “sunos5” platform.

## **1.2b3 (2010-02-28)**

- Only provide simplification implementations for GEOS C API  $\geq 1.5$ .

## **1.2b2 (2010-02-19)**

- Fix cascaded\_union bug introduced in 1.2b1 (#212).

### 1.2b1 (2010-02-18)

- Update the README. Remove cruft from setup.py. Add some version 1.2 metadata regarding required Python version ( $\geq 2.5, < 3$ ) and external dependency (`libgeos_c`  $\geq 3.1$ ).

### 1.2a6 (2010-02-09)

- Add accessor for separate arrays of X and Y values (#210).

TODO: fill gap here

### 1.2a1 (2010-01-20)

- Proper prototyping of WKB writer, and avoidance of errors on 64-bit systems (#191).
- Prototype `libgeos_c` functions in a way that lets py2exe apps import shapely (#189).

1.2 Branched (2009-09-19)

### 1.0.12 (2009-04-09)

- Fix for references held by topology and predicate descriptors.

### 1.0.11 (2008-11-20)

- Work around bug in GEOS 2.2.3, `GEOSCoordSeq_getOrdinate` not exported properly (#178).

### 1.0.10 (2008-11-17)

- Fixed compatibility with GEOS 2.2.3 that was broken in 1.0.8 release (#176).

### 1.0.9 (2008-11-16)

- Find and load MacPorts `libgeos`.

### 1.0.8 (2008-11-01)

- Fill out GEOS function result and argument types to prevent faults on a 64-bit arch.

### 1.0.7 (2008-08-22)

- Polygon rings now have the same dimensions as parent (#168).
- Eliminated reference cycles in polygons (#169).

### 1.0.6 (2008-07-10)

- Fixed adaptation of multi polygon data.
- Raise exceptions earlier from binary predicates.
- Beginning distributing new windows DLLs (#166).

### 1.0.5 (2008-05-20)

- Added access to GEOS polygonizer function.
- Raise exception when insufficient coordinate tuples are passed to LinearRing constructor (#164).

### 1.0.4 (2008-05-01)

- Disentangle Python and topological equality (#163).
- Add shape(), a factory that copies coordinates from a geo interface provider. To be used instead of asShape() unless you really need to store coordinates outside shapely for efficient use in other code.
- Cache GEOS geometries in adapters (#163).

### 1.0.3 (2008-04-09)

- Do not release GIL when calling GEOS functions (#158).
- Prevent faults when chaining multiple GEOS operators (#159).

### 1.0.2 (2008-02-26)

- Fix loss of dimensionality in polygon rings (#155).

### 1.0.1 (2008-02-08)

- Allow chaining expressions involving coordinate sequences and geometry parts (#151).
- Protect against abnormal use of coordinate accessors (#152).
- Coordinate sequences now implement the numpy array protocol (#153).

### 1.0 (2008-01-18)

- Final release.

## 1.0 RC2 (2008-01-16)

- Added temporary solution for #149.

## 1.0 RC1 (2008-01-14)

- First release candidate

## 1.1.9 Frequently asked questions and answers

### I installed shapely in a conda environment using pip. Why doesn't it work?

Shapely versions < 2.0 load a GEOS shared library using ctypes. It's not uncommon for users to have multiple copies of GEOS libs on their system. Loading the correct one is complicated and shapely has a number of platform-dependent GEOS library loading bugs. The project has particularly poor support for finding the correct GEOS library for a shapely package installed from PyPI *into* a conda environment. We recommend that conda users always get shapely from conda-forge.

### Are there references for the algorithms used by shapely?

Generally speaking, shapely's predicates and operations are derived from methods of the same name from [GEOS](#) and the [JTS Topology Suite](#). See the [JTS FAQ](#) for references describing the JTS algorithms.

### I used `.buffer()` on a geometry with Z coordinates. Where did the Z coordinates go?

The buffer algorithm in [GEOS](#) is purely two-dimensional and discards any Z coordinates. This is generally the case for the GEOS algorithms.

## 1.2 The Shapely User Manual

**Author** Sean Gillies, <[sean.gillies@gmail.com](mailto:sean.gillies@gmail.com)>

**Version** 1.7.0

**Date** Dec 17, 2021

**Copyright** This work is licensed under a [Creative Commons Attribution 3.0 United States License](#).

**Abstract** This document explains how to use the Shapely Python package for computational geometry.

### 1.2.1 Introduction

Deterministic spatial analysis is an important component of computational approaches to problems in agriculture, ecology, epidemiology, sociology, and many other fields. What is the surveyed perimeter/area ratio of these patches of animal habitat? Which properties in this town intersect with the 50-year flood contour from this new flooding model? What are the extents of findspots for ancient ceramic wares with maker's marks "A" and "B", and where do the extents overlap? What's the path from home to office that best skirts identified zones of location based spam? These are just a few of the possible questions addressable using non-statistical spatial analysis, and more specifically, computational geometry.

Shapely is a Python package for set-theoretic analysis and manipulation of planar features using (via Python's `ctypes` module) functions from the well known and widely deployed [GEOS](#) library. GEOS, a port of the [Java Topology Suite](#) (JTS), is the geometry engine of the [PostGIS](#) spatial extension for the PostgreSQL RDBMS. The designs of JTS and GEOS are largely guided by the [Open Geospatial Consortium](#)'s Simple Features Access Specification<sup>1</sup> and Shapely adheres mainly to the same set of standard classes and operations. Shapely is thereby deeply rooted in the conventions of the geographic information systems (GIS) world, but aspires to be equally useful to programmers working on non-conventional problems.

The first premise of Shapely is that Python programmers should be able to perform PostGIS type geometry operations outside of an RDBMS. Not all geographic data originate or reside in a RDBMS or are best processed using SQL. We can load data into a spatial RDBMS to do work, but if there's no mandate to manage (the "M" in "RDBMS") the data over time in the database we're using the wrong tool for the job. The second premise is that the persistence, serialization, and map projection of features are significant, but orthogonal problems. You may not need a hundred GIS format readers and writers or the multitude of State Plane projections, and Shapely doesn't burden you with them. The third premise is that Python idioms trump GIS (or Java, in this case, since the GEOS library is derived from JTS, a Java project) idioms.

If you enjoy and profit from idiomatic Python, appreciate packages that do one thing well, and agree that a spatially enabled RDBMS is often enough the wrong tool for your computational geometry job, Shapely might be for you.

### Spatial Data Model

The fundamental types of geometric objects implemented by Shapely are points, curves, and surfaces. Each is associated with three sets of (possibly infinite) points in the plane. The *interior*, *boundary*, and *exterior* sets of a feature are mutually exclusive and their union coincides with the entire plane<sup>2</sup>.

- A *Point* has an *interior* set of exactly one point, a *boundary* set of exactly no points, and an *exterior* set of all other points. A *Point* has a topological dimension of 0.
- A *Curve* has an *interior* set consisting of the infinitely many points along its length (imagine a *Point* dragged in space), a *boundary* set consisting of its two end points, and an *exterior* set of all other points. A *Curve* has a topological dimension of 1.
- A *Surface* has an *interior* set consisting of the infinitely many points within (imagine a *Curve* dragged in space to cover an area), a *boundary* set consisting of one or more *Curves*, and an *exterior* set of all other points including those within holes that might exist in the surface. A *Surface* has a topological dimension of 2.

That may seem a bit esoteric, but will help clarify the meanings of Shapely's spatial predicates, and it's as deep into theory as this manual will go. Consequences of point-set theory, including some that manifest themselves as "gotchas", for different classes will be discussed later in this manual.

The point type is implemented by a *Point* class; curve by the *LineString* and *LinearRing* classes; and surface by a *Polygon* class. Shapely implements no smooth (*i.e.* having continuous tangents) curves. All curves must be approximated by linear splines. All rounded patches must be approximated by regions bounded by linear splines.

Collections of points are implemented by a *MultiPoint* class, collections of curves by a *MultiLineString* class, and collections of surfaces by a *MultiPolygon* class. These collections aren't computationally significant, but are useful for modeling certain kinds of features. A Y-shaped line feature, for example, is well modeled as a whole by a *MultiLineString*.

The standard data model has additional constraints specific to certain types of geometric objects that will be discussed in following sections of this manual.

See also <https://web.archive.org/web/20160719195511/http://www.vividsolutions.com/jts/discussion.htm> for more illustrations of this data model.

## Relationships

The spatial data model is accompanied by a group of natural language relationships between geometric objects – *contains*, *intersects*, *overlaps*, *touches*, etc. – and a theoretical framework for understanding them using the 3x3 matrix of the mutual intersections of their component point sets<sup>3</sup>: the DE-9IM. A comprehensive review of the relationships in terms of the DE-9IM is found in<sup>4</sup> and will not be reiterated in this manual.

## Operations

Following the JTS technical specs<sup>5</sup>, this manual will make a distinction between constructive (*buffer*, *convex hull*) and set-theoretic operations (*intersection*, *union*, etc.). The individual operations will be fully described in a following section of the manual.

## Coordinate Systems

Even though the Earth is not flat – and for that matter not exactly spherical – there are many analytic problems that can be approached by transforming Earth features to a Cartesian plane, applying tried and true algorithms, and then transforming the results back to geographic coordinates. This practice is as old as the tradition of accurate paper maps.

Shapely does not support coordinate system transformations. All operations on two or more features presume that the features exist in the same Cartesian plane.

### 1.2.2 Geometric Objects

Geometric objects are created in the typical Python fashion, using the classes themselves as instance factories. A few of their intrinsic properties will be discussed in this sections, others in the following sections on operations and serializations.

Instances of `Point`, `LineString`, and `LinearRing` have as their most important attribute a finite sequence of coordinates that determines their interior, boundary, and exterior point sets. A line string can be determined by as few as 2 points, but contains an infinite number of points. Coordinate sequences are immutable. A third *z* coordinate value may be used when constructing instances, but has no effect on geometric analysis. All operations are performed in the *x-y* plane.

In all constructors, numeric values are converted to type `float`. In other words, `Point(0, 0)` and `Point(0.0, 0.0)` produce geometrically equivalent instances. Shapely does not check the topological simplicity or validity of instances when they are constructed as the cost is unwarranted in most cases. Validating factories are easily implemented using the `:attr:is_valid` predicate by users that require them.

---

**Note:** Shapely is a planar geometry library and *z*, the height above or below the plane, is ignored in geometric analysis. There is a potential pitfall for users here: coordinate tuples that differ only in *z* are not distinguished from each other and their application can result in suprisingly invalid geometry objects. For example, `LineString([(0, 0, 0),`

Di Felice, and P. van Oosterom, “A Small Set of Formal Topological Relationships Suitable for End-User Interaction,” Third International Symposium on Large Spatial Databases (SSD). Lecture Notes in Computer Science no. 692, David Abel and Beng Chin Ooi, Eds., Singapore: Springer Verlag, 1993, pp. 277-295.

<sup>4</sup> C. Strobl, “Dimensionally Extended Nine-Intersection Model (DE-9IM),” Encyclopedia of GIS, S. Shekhar and H. Xiong, Eds., Springer, 2008, pp. 240-245. [PDF]

<sup>5</sup> Martin Davis, “JTS Technical Specifications,” Mar. 2003. [PDF]

`(0, 0, 1)])` does not return a vertical line of unit length, but an invalid line in the plane with zero length. Similarly, `Polygon([(0, 0, 0), (0, 0, 1), (1, 1, 1)])` is not bounded by a closed ring and is invalid.

---

### General Attributes and Methods

#### `object.area`

Returns the area (float) of the object.

#### `object.bounds`

Returns a (minx, miny, maxx, maxy) tuple (float values) that bounds the object.

#### `object.length`

Returns the length (float) of the object.

#### `object.minimum_clearance`

Returns the smallest distance by which a node could be moved to produce an invalid geometry.

This can be thought of as a measure of the robustness of a geometry, where larger values of minimum clearance indicate a more robust geometry. If no minimum clearance exists for a geometry, such as a point, this will return *math.inf*.

*New in Shapely 1.7.1*

Requires GEOS 3.6 or higher.

```
>>> from shapely.geometry import Polygon
>>> Polygon([(0, 0), (1, 0), (1, 1), (0, 1), (0, 0)]).minimum_clearance
1.0
```

#### `object.geom_type`

Returns a string specifying the *Geometry Type* of the object in accordance with<sup>?</sup>.

```
>>> Point(0, 0).geom_type
'Point'
```

#### `object.distance(other)`

Returns the minimum distance (float) to the *other* geometric object.

```
>>> Point(0,0).distance(Point(1,1))
1.4142135623730951
```

#### `object.hausdorff_distance(other)`

Returns the Hausdorff distance (float) to the *other* geometric object. The Hausdorff distance between two geometries is the furthest distance that a point on either geometry can be from the nearest point to it on the other geometry.

*New in Shapely 1.6.0*

```
>>> point = Point(1, 1)
>>> line = LineString([(2, 0), (2, 4), (3, 4)])
>>> point.hausdorff_distance(line)
3.605551275463989
>>> point.distance(Point(3, 4))
3.605551275463989
```

#### `object.representative_point()`

Returns a cheaply computed point that is guaranteed to be within the geometric object.

---

**Note:** This is not in general the same as the centroid.

---

```
>>> donut = Point(0, 0).buffer(2.0).difference(Point(0, 0).buffer(1.0))
>>> donut.centroid.wkt
'POINT (-0.000000000000000001 -0.000000000000000000)'
>>> donut.representative_point().wkt
'POINT (-1.5000000000000000 0.0000000000000000)'
```

## Points

**class** `Point(coordinates)`

The *Point* constructor takes positional coordinate values or point tuple parameters.

```
>>> from shapely.geometry import Point
>>> point = Point(0.0, 0.0)
>>> q = Point((0.0, 0.0))
```

A *Point* has zero area and zero length.

```
>>> point.area
0.0
>>> point.length
0.0
```

Its *x-y* bounding box is a (minx, miny, maxx, maxy) tuple.

```
>>> point.bounds
(0.0, 0.0, 0.0, 0.0)
```

Coordinate values are accessed via *coords*, *x*, *y*, and *z* properties.

```
>>> list(point.coords)
[(0.0, 0.0)]
>>> point.x
0.0
>>> point.y
0.0
```

Coordinates may also be sliced. *New in version 1.2.14.*

```
>>> point.coords[:]
[(0.0, 0.0)]
```

The *Point* constructor also accepts another *Point* instance, thereby making a copy.

```
>>> Point(point)
<shapely.geometry.point.Point object at 0x...>
```

## LineStrings

**class** `LineString(coordinates)`

The `LineString` constructor takes an ordered sequence of 2 or more (x, y[, z]) point tuples.

The constructed `LineString` object represents one or more connected linear splines between the points. Repeated points in the ordered sequence are allowed, but may incur performance penalties and should be avoided. A `LineString` may cross itself (i.e. be *complex* and not *simple*).

Figure 1. A simple `LineString` on the left, a complex `LineString` on the right. The (*MultiPoint*) boundary of each is shown in black, the other points that describe the lines are shown in grey.

A `LineString` has zero area and non-zero length.

```
>>> from shapely.geometry import LineString
>>> line = LineString([(0, 0), (1, 1)])
>>> line.area
0.0
>>> line.length
1.4142135623730951
```

Its x-y bounding box is a (minx, miny, maxx, maxy) tuple.

```
>>> line.bounds
(0.0, 0.0, 1.0, 1.0)
```

The defining coordinate values are accessed via the `coords` property.

```
>>> len(line.coords)
2
```

(continues on next page)

(continued from previous page)

```
>>> list(line.coords)
[(0.0, 0.0), (1.0, 1.0)]
```

Coordinates may also be sliced. *New in version 1.2.14.*

```
>>> point.coords[:]
[(0.0, 0.0), (1.0, 1.0)]
>>> point.coords[1:]
[(1.0, 1.0)]
```

The constructor also accepts another *LineString* instance, thereby making a copy.

```
>>> LineString(line)
<shapely.geometry.linestring.LineString object at 0x...>
```

A *LineString* may also be constructed using a sequence of mixed *Point* instances or coordinate tuples. The individual coordinates are copied into the new object.

```
>>> LineString([Point(0.0, 1.0), (2.0, 3.0), Point(4.0, 5.0)])
<shapely.geometry.linestring.LineString object at 0x...>
```

## LinearRings

**class** *LinearRing*(*coordinates*)

The *LinearRing* constructor takes an ordered sequence of (*x*, *y* [, *z*]) point tuples.

The sequence may be explicitly closed by passing identical values in the first and last indices. Otherwise, the sequence will be implicitly closed by copying the first tuple to the last index. As with a *LineString*, repeated points in the ordered sequence are allowed, but may incur performance penalties and should be avoided. A *LinearRing* may not cross itself, and may not touch itself at a single point.

Figure 2. A valid *LinearRing* on the left, an invalid self-touching *LinearRing* on the right. The points that describe the rings are shown in grey. A ring's boundary is *empty*.

---

**Note:** Shapely will not prevent the creation of such rings, but exceptions will be raised when they are operated on.

---

A *LinearRing* has zero area and non-zero length.

```
>>> from shapely.geometry.polygon import LinearRing
>>> ring = LinearRing([(0, 0), (1, 1), (1, 0)])
>>> ring.area
0.0
>>> ring.length
3.4142135623730949
```

Its *x-y* bounding box is a (*minx*, *miny*, *maxx*, *maxy*) tuple.

```
>>> ring.bounds
(0.0, 0.0, 1.0, 1.0)
```

Defining coordinate values are accessed via the *coords* property.

```
>>> len(ring.coords)
4
>>> list(ring.coords)
[(0.0, 0.0), (1.0, 1.0), (1.0, 0.0), (0.0, 0.0)]
```

The *LinearRing* constructor also accepts another *LineString* or *LinearRing* instance, thereby making a copy.

```
>>> LinearRing(ring)
<shapely.geometry.polygon.LinearRing object at 0x...>
```

As with *LineString*, a sequence of *Point* instances is not a valid constructor parameter.

## Polygons

**class Polygon(shell[, holes=None])**

The *Polygon* constructor takes two positional parameters. The first is an ordered sequence of (x, y[, z]) point tuples and is treated exactly as in the *LinearRing* case. The second is an optional unordered sequence of ring-like sequences specifying the interior boundaries or “holes” of the feature.

Rings of a *valid Polygon* may not cross each other, but may touch at a single point only. Again, Shapely will not prevent the creation of invalid features, but exceptions will be raised when they are operated on.

Figure 3. On the left, a *valid Polygon* with one interior ring that touches the exterior ring at one point, and on the right a *Polygon* that is *invalid* because its interior ring touches the exterior ring at more than one point. The points that describe the rings are shown in grey.

Figure 4. On the left, a *Polygon* that is *invalid* because its exterior and interior rings touch along a line, and on the right, a *Polygon* that is *invalid* because its interior rings touch along a line.

A *Polygon* has non-zero area and non-zero length.

```
>>> from shapely.geometry import Polygon
>>> polygon = Polygon([(0, 0), (1, 1), (1, 0)])
>>> polygon.area
0.5
>>> polygon.length
3.4142135623730949
```

Its *x-y* bounding box is a (minx, miny, maxx, maxy) tuple.

```
>>> polygon.bounds
(0.0, 0.0, 1.0, 1.0)
```

Component rings are accessed via *exterior* and *interiors* properties.

```
>>> list(polygon.exterior.coords)
[(0.0, 0.0), (1.0, 1.0), (1.0, 0.0), (0.0, 0.0)]
>>> list(polygon.interiors)
[]
```

The *Polygon* constructor also accepts instances of *LineString* and *LinearRing*.

```
>>> coords = [(0, 0), (1, 1), (1, 0)]
>>> r = LinearRing(coords)
>>> s = Polygon(r)
>>> s.area
0.5
>>> t = Polygon(s.buffer(1.0).exterior, [r])
>>> t.area
6.5507620529190334
```

Rectangular polygons occur commonly, and can be conveniently constructed using the *shapely.geometry.box()* function.

**shapely.geometry.box(minx, miny, maxx, maxy, ccw=True)**

Makes a rectangular polygon from the provided bounding box values, with counter-clockwise order by default.

*New in version 1.2.9.*

For example:

```
>>> from shapely.geometry import box
>>> b = box(0.0, 0.0, 1.0, 1.0)
>>> b
<shapely.geometry.polygon.Polygon object at 0x...>
>>> list(b.exterior.coords)
[(1.0, 0.0), (1.0, 1.0), (0.0, 1.0), (0.0, 0.0), (1.0, 0.0)]
```

This is the first appearance of an explicit polygon handedness in Shapely.

To obtain a polygon with a known orientation, use *shapely.geometry.polygon.orient()*:

**shapely.geometry.polygon.orient(polygon, sign=1.0)**

Returns a properly oriented copy of the given polygon. The signed area of the result will have the given sign. A sign of 1.0 means that the coordinates of the product's exterior ring will be oriented counter-clockwise and the interior rings (holes) will be oriented clockwise.

New in version 1.2.10.

## Collections

Heterogeneous collections of geometric objects may result from some Shapely operations. For example, two *LineStrings* may intersect along a line and at a point. To represent these kind of results, Shapely provides *frozenset*-like, immutable collections of geometric objects. The collections may be homogeneous (*MultiPoint* etc.) or heterogeneous.

```
>>> a = LineString([(0, 0), (1, 1), (1,2), (2,2)])
>>> b = LineString([(0, 0), (1, 1), (2,1), (2,2)])
>>> x = a.intersection(b)
>>> x
<shapely.geometry.collection.GeometryCollection object at 0x...>
>>> from pprint import pprint
>>> pprint(list(x))
[<shapely.geometry.point.Point object at 0x...>,
 <shapely.geometry.linestring.LineString object at 0x...>]
```

Figure 5. a) a green and a yellow line that intersect along a line and at a single point; b) the intersection (in blue) is a collection containing one *LineString* and one *Point*.

Members of a *GeometryCollection* are accessed via the `geoms` property or via the iterator protocol using `in` or `list()`.

```
>>> pprint(list(x.geoms))
[<shapely.geometry.point.Point object at 0x...>,
 <shapely.geometry.linestring.LineString object at 0x...>]
>>> pprint(list(x))
```

(continues on next page)

(continued from previous page)

```
[<shapely.geometry.point.Point object at 0x...>,
 <shapely.geometry.linestring.LineString object at 0x...>]
```

Collections can also be sliced.

```
>>> from shapely.geometry import MultiPoint
>>> m = MultiPoint([(0, 0), (1, 1), (1,2), (2,2)])
>>> m[:1].wkt
'MULTIPOINT (0.0000000000000000 0.0000000000000000)'
>>> m[3:].wkt
'MULTIPOINT (2.0000000000000000 2.0000000000000000)'
>>> m[4:].wkt
'GEOMETRYCOLLECTION EMPTY'
```

*New in version 1.2.14.*

---

**Note:** When possible, it is better to use one of the homogeneous collection types described below.

---

## Collections of Points

**class** `MultiPoint`(*points*)

The *MultiPoint* constructor takes a sequence of (x, y[, z ]) point tuples.

A *MultiPoint* has zero area and zero length.

```
>>> from shapely.geometry import MultiPoint
>>> points = MultiPoint([(0.0, 0.0), (1.0, 1.0)])
>>> points.area
0.0
>>> points.length
0.0
```

Its x-y bounding box is a (minx, miny, maxx, maxy) tuple.

```
>>> points.bounds
(0.0, 0.0, 1.0, 1.0)
```

Members of a multi-point collection are accessed via the `geoms` property or via the iterator protocol using `in` or `list()`.

```
>>> import pprint
>>> pprint.pprint(list(points.geoms))
[<shapely.geometry.point.Point object at 0x...>,
 <shapely.geometry.point.Point object at 0x...>]
>>> pprint.pprint(list(points))
[<shapely.geometry.point.Point object at 0x...>,
 <shapely.geometry.point.Point object at 0x...>]
```

The constructor also accepts another *MultiPoint* instance or an unordered sequence of *Point* instances, thereby making copies.

```
>>> MultiPoint([Point(0, 0), Point(1, 1)])
<shapely.geometry.multipoint.MultiPoint object at 0x...>
```

## Collections of Lines

**class MultiLineString(*lines*)**

The *MultiLineString* constructor takes a sequence of line-like sequences or objects.

Figure 6. On the left, a *simple*, disconnected *MultiLineString*, and on the right, a non-simple *MultiLineString*. The points defining the objects are shown in gray, the boundaries of the objects in black.

A *MultiLineString* has zero area and non-zero length.

```
>>> from shapely.geometry import MultiLineString
>>> coords = [((0, 0), (1, 1)), ((-1, 0), (1, 0))]
>>> lines = MultiLineString(coords)
>>> lines.area
0.0
>>> lines.length
3.4142135623730949
```

Its *x-y* bounding box is a (*minx*, *miny*, *maxx*, *maxy*) tuple.

```
>>> lines.bounds
(-1.0, 0.0, 1.0, 1.0)
```

Its members are instances of *LineString* and are accessed via the *geoms* property or via the iterator protocol using *in* or *list()*.

```
>>> len(lines.geoms)
2
>>> pprint.pprint(list(lines.geoms))
```

(continues on next page)

(continued from previous page)

```
[<shapely.geometry.linestring.LineString object at 0x...>,
 <shapely.geometry.linestring.LineString object at 0x...>]
>>> pprint.pprint(list(lines))
[<shapely.geometry.linestring.LineString object at 0x...>,
 <shapely.geometry.linestring.LineString object at 0x...>]
```

The constructor also accepts another instance of *MultiLineString* or an unordered sequence of *LineString* instances, thereby making copies.

```
>>> MultiLineString(lines)
<shapely.geometry.multilinestring.MultiLineString object at 0x...>
>>> MultiLineString(lines.geoms)
<shapely.geometry.multilinestring.MultiLineString object at 0x...>
```

## Collections of Polygons

**class** *MultiPolygon*(*polygons*)

The *MultiPolygon* constructor takes a sequence of exterior ring and hole list tuples: `[((a1, ..., aM), [(b1, ..., bN), ...]), ...]`.

More clearly, the constructor also accepts an unordered sequence of *Polygon* instances, thereby making copies.

```
>>> polygons = MultiPolygon([polygon, s, t])
>>> len(polygons.geoms)
3
```

Figure 7. On the left, a *valid MultiPolygon* with 2 members, and on the right, a *MultiPolygon* that is invalid because its

members touch at an infinite number of points (along a line).

Its  $x$ - $y$  bounding box is a (minx, miny, maxx, maxy) tuple.

```
>>> polygons.bounds
(-1.0, -1.0, 2.0, 2.0)
```

Its members are instances of *Polygon* and are accessed via the `geoms` property.

```
>>> len(polygons.geoms)
3
```

## Empty features

An “empty” feature is one with a point set that coincides with the empty set; not `None`, but like `set([])`. Empty features can be created by calling the various constructors with no arguments. Almost no operations are supported by empty features.

```
>>> line = LineString()
>>> line.is_empty
True
>>> line.length
0.0
>>> line.bounds
()
>>> line.coords
[]
```

The coordinates of an empty feature can be set, after which the geometry is no longer empty.

```
>>> line.coords = [(0, 0), (1, 1)]
>>> line.is_empty
False
>>> line.length
1.4142135623730951
>>> line.bounds
(0.0, 0.0, 1.0, 1.0)
```

## Coordinate sequences

The list of coordinates that describe a geometry are represented as the `CoordinateSequence` object. These sequences should not be initialised directly, but can be accessed from an existing geometry as the `Geometry.coords` property.

```
>>> line = LineString([(0, 1), (2, 3), (4, 5)])
>>> line.coords
<shapely.coords.CoordinateSequence object at 0x000000276EED1C7F0>
```

Coordinate sequences can be indexed, sliced and iterated over as if they were a list of coordinate tuples.

```
>>> line.coords[0]
(0.0, 1.0)
>>> line.coords[1:]
```

(continues on next page)

(continued from previous page)

```
[(2.0, 3.0), (4.0, 5.0)]
>>> for x, y in line.coords:
...     print("x={}, y={}".format(x, y))
...
x=0.0, y=1.0
x=2.0, y=3.0
x=4.0, y=5.0
```

Polygons have a coordinate sequence for their exterior and each of their interior rings.

```
>>> poly = Polygon([(0, 0), (0, 1), (1, 1), (0, 0)])
>>> poly.exterior.coords
<shapely.coords.CoordinateSequence object at 0x000000276EED1C048>
```

Multipart geometries do not have a coordinate sequence. Instead the coordinate sequences are stored on their component geometries.

```
>>> p = MultiPoint([(0, 0), (1, 1), (2, 2)])
>>> p[2].coords
<shapely.coords.CoordinateSequence object at 0x000000276EFB9B320>
```

## Linear Referencing Methods

It can be useful to specify position along linear features such as *LineStrings* and *MultiLineStrings* with a 1-dimensional referencing system. Shapely supports linear referencing based on length or distance, evaluating the distance along a geometric object to the projection of a given point, or the point at a given distance along the object.

**object.interpolate(*distance* [, *normalized=False* ])**

Return a point at the specified distance along a linear geometric object.

If the *normalized* arg is *True*, the distance will be interpreted as a fraction of the geometric object's length.

```
>>> ip = LineString([(0, 0), (0, 1), (1, 1)]).interpolate(1.5)
>>> ip
<shapely.geometry.point.Point object at 0x740570>
>>> ip.wkt
'POINT (0.5000000000000000 1.0000000000000000)'
>>> LineString([(0, 0), (0, 1), (1, 1)]).interpolate(0.75, normalized=True).wkt
'POINT (0.5000000000000000 1.0000000000000000)'
```

**object.project(*other* [, *normalized=False* ])**

Returns the distance along this geometric object to a point nearest the *other* object.

If the *normalized* arg is *True*, return the distance normalized to the length of the object. The *project()* method is the inverse of *interpolate()*.

```
>>> LineString([(0, 0), (0, 1), (1, 1)]).project(ip)
1.5
>>> LineString([(0, 0), (0, 1), (1, 1)]).project(ip, normalized=True)
0.75
```

For example, the linear referencing methods might be used to cut lines at a specified distance.

```
def cut(line, distance):
    # Cuts a line in two at a distance from its starting point
    if distance <= 0.0 or distance >= line.length:
        return [LineString(line)]
    coords = list(line.coords)
    for i, p in enumerate(coords):
        pd = line.project(Point(p))
        if pd == distance:
            return [
                LineString(coords[:i+1]),
                LineString(coords[i:])]
        if pd > distance:
            cp = line.interpolate(distance)
            return [
                LineString(coords[:i] + [(cp.x, cp.y)]),
                LineString([(cp.x, cp.y)] + coords[i:])]

```

```
>>> line = LineString([(0, 0), (1, 0), (2, 0), (3, 0), (4, 0), (5, 0)])
>>> pprint([list(x.coords) for x in cut(line, 1.0)])
[[ (0.0, 0.0), (1.0, 0.0) ],
 [ (1.0, 0.0), (2.0, 0.0), (3.0, 0.0), (4.0, 0.0), (5.0, 0.0) ]]
>>> pprint([list(x.coords) for x in cut(line, 2.5)])
[[ (0.0, 0.0), (1.0, 0.0), (2.0, 0.0), (2.5, 0.0) ],
 [ (2.5, 0.0), (3.0, 0.0), (4.0, 0.0), (5.0, 0.0) ]]

```

## 1.2.3 Predicates and Relationships

Objects of the types explained in *Geometric Objects* provide standard<sup>2</sup> predicates as attributes (for unary predicates) and methods (for binary predicates). Whether unary or binary, all return True or False.

### Unary Predicates

Standard unary predicates are implemented as read-only property attributes. An example will be shown for each.

#### `object.has_z`

Returns True if the feature has not only *x* and *y*, but also *z* coordinates for 3D (or so-called, 2.5D) geometries.

```
>>> Point(0, 0).has_z
False
>>> Point(0, 0, 0).has_z
True

```

#### `object.is_ccw`

Returns True if coordinates are in counter-clockwise order (bounding a region with positive signed area). This method applies to *LinearRing* objects only.

*New in version 1.2.10.*

```
>>> LinearRing([(1,0), (1,1), (0,0)]).is_ccw
True

```

A ring with an undesired orientation can be reversed like this:

```
>>> ring = LinearRing([(0,0), (1,1), (1,0)])
>>> ring.is_ccw
False
>>> ring.coords = list(ring.coords)[::-1]
>>> ring.is_ccw
True
```

### `object.is_empty`

Returns True if the feature's *interior* and *boundary* (in point set terms) coincide with the empty set.

```
>>> Point().is_empty
True
>>> Point(0, 0).is_empty
False
```

---

**Note:** With the help of the operator module's `attrgetter()` function, unary predicates such as `is_empty` can be easily used as predicates for the built in `filter()` or `itertools.ifilter()`.

---

```
>>> from operator import attrgetter
>>> empties = filter(attrgetter('is_empty'), [Point(), Point(0, 0)])
>>> len(empties)
1
```

### `object.is_ring`

Returns True if the feature is a closed and simple *LineString*. A closed feature's *boundary* coincides with the empty set.

```
>>> LineString([(0, 0), (1, 1), (1, -1)]).is_ring
False
>>> LinearRing([(0, 0), (1, 1), (1, -1)]).is_ring
True
```

This property is applicable to *LineString* and *LinearRing* instances, but meaningless for others.

### `object.is_simple`

Returns True if the feature does not cross itself.

---

**Note:** The simplicity test is meaningful only for *LineStrings* and *LinearRings*.

---

```
>>> LineString([(0, 0), (1, 1), (1, -1), (0, 1)]).is_simple
False
```

Operations on non-simple *LineStrings* are fully supported by Shapely.

### `object.is_valid`

Returns True if a feature is “valid” in the sense of<sup>?</sup>.

---

**Note:** The validity test is meaningful only for *Polygons* and *MultiPolygons*. True is always returned for other types of geometries.

---

A valid *Polygon* may not possess any overlapping exterior or interior rings. A valid *MultiPolygon* may not collect any overlapping polygons. Operations on invalid features may fail.

```
>>> MultiPolygon([Point(0, 0).buffer(2.0), Point(1, 1).buffer(2.0)]).is_valid
False
```

The two points above are close enough that the polygons resulting from the buffer operations (explained in a following section) overlap.

**Note:** The `is_valid` predicate can be used to write a validating decorator that could ensure that only valid objects are returned from a constructor function.

```
from functools import wraps
def validate(func):
    @wraps(func)
    def wrapper(*args, **kwargs):
        ob = func(*args, **kwargs)
        if not ob.is_valid:
            raise TopologicalError(
                "Given arguments do not determine a valid geometric object")
        return ob
    return wrapper
```

```
>>> @validate
... def ring(coordinates):
...     return LinearRing(coordinates)
...
>>> coords = [(0, 0), (1, 1), (1, -1), (0, 1)]
>>> ring(coords)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
  File "<stdin>", line 7, in wrapper
shapely.geos.TopologicalError: Given arguments do not determine a valid geometric object
```

## Binary Predicates

Standard binary predicates are implemented as methods. These predicates evaluate topological, set-theoretic relationships. In a few cases the results may not be what one might expect starting from different assumptions. All take another geometric object as argument and return `True` or `False`.

`object.__eq__(other)`

Returns `True` if the two objects are of the same geometric type, and the coordinates of the two objects match precisely.

`object.equals(other)`

Returns `True` if the set-theoretic *boundary*, *interior*, and *exterior* of the object coincide with those of the other.

The coordinates passed to the object constructors are of these sets, and determine them, but are not the entirety of the sets. This is a potential “gotcha” for new users. Equivalent lines, for example, can be constructed differently.

```
>>> a = LineString([(0, 0), (1, 1)])
>>> b = LineString([(0, 0), (0.5, 0.5), (1, 1)])
```

(continues on next page)

(continued from previous page)

```
>>> c = LineString([(0, 0), (0, 0), (1, 1)])
>>> a.equals(b)
True
>>> a == b
False
>>> b.equals(c)
True
>>> b == c
False
```

`object.almost_equals(other[, decimal=6])`

Returns True if the object is approximately equal to the *other* at all points to specified *decimal* place precision.

`object.contains(other)`

Returns True if no points of *other* lie in the exterior of the *object* and at least one point of the interior of *other* lies in the interior of *object*.

This predicate applies to all types, and is inverse to `within()`. The expression `a.contains(b) == b.within(a)` always evaluates to True.

```
>>> coords = [(0, 0), (1, 1)]
>>> LineString(coords).contains(Point(0.5, 0.5))
True
>>> Point(0.5, 0.5).within(LineString(coords))
True
```

A line's endpoints are part of its *boundary* and are therefore not contained.

```
>>> LineString(coords).contains(Point(1.0, 1.0))
False
```

---

**Note:** Binary predicates can be used directly as predicates for `filter()` or `itertools.ifilter()`.

---

```
>>> line = LineString(coords)
>>> contained = filter(line.contains, [Point(), Point(0.5, 0.5)])
>>> len(contained)
1
>>> [p.wkt for p in contained]
['POINT (0.5000000000000000 0.5000000000000000)']
```

`object.covers(other)`

Returns True if every point of *other* is a point on the interior or boundary of *object*. This is similar to `object.contains(other)` except that this does not require any interior points of *other* to lie in the interior of *object*.

`object.covered_by(other)`

Returns True if every point of *object* is a point on the interior or boundary of *other*. This is equivalent to `other.covers(object)`.

*New in version 1.8.*

`object.crosses(other)`

Returns True if the *interior* of the object intersects the *interior* of the other but does not contain it, and the dimension of the intersection is less than the dimension of the one or the other.

```
>>> LineString(coords).crosses(LineString([(0, 1), (1, 0)]))
True
```

A line does not cross a point that it contains.

```
>>> LineString(coords).crosses(Point(0.5, 0.5))
False
```

**object.disjoint(*other*)**

Returns True if the *boundary* and *interior* of the object do not intersect at all with those of the other.

```
>>> Point(0, 0).disjoint(Point(1, 1))
True
```

This predicate applies to all types and is the inverse of `intersects()`.

**object.intersects(*other*)**

Returns True if the *boundary* or *interior* of the object intersect in any way with those of the other.

In other words, geometric objects intersect if they have any boundary or interior point in common.

**object.overlaps(*other*)**

Returns True if the geometries have more than one but not all points in common, have the same dimension, and the intersection of the interiors of the geometries has the same dimension as the geometries themselves.

**object.touches(*other*)**

Returns True if the objects have at least one point in common and their interiors do not intersect with any part of the other.

Overlapping features do not therefore *touch*, another potential “gotcha”. For example, the following lines touch at (1, 1), but do not overlap.

```
>>> a = LineString([(0, 0), (1, 1)])
>>> b = LineString([(1, 1), (2, 2)])
>>> a.touches(b)
True
```

**object.within(*other*)**

Returns True if the object’s *boundary* and *interior* intersect only with the *interior* of the other (not its *boundary* or *exterior*).

This applies to all types and is the inverse of `contains()`.

Used in a `sorted()` key, `within()` makes it easy to spatially sort objects. Let’s say we have 4 stereotypic features: a point that is contained by a polygon which is itself contained by another polygon, and a free spirited point contained by none

```
>>> a = Point(2, 2)
>>> b = Polygon([[1, 1], [1, 3], [3, 3], [3, 1]])
>>> c = Polygon([[0, 0], [0, 4], [4, 4], [4, 0]])
>>> d = Point(-1, -1)
```

and that copies of these are collected into a list

```
>>> features = [c, a, d, b, c]
```

that we'd prefer to have ordered as [d, c, c, b, a] in reverse containment order. As explained in the Python [Sorting HowTo](#), we can define a key function that operates on each list element and returns a value for comparison. Our key function will be a wrapper class that implements `__lt__()` using Shapely's binary `within()` predicate.

```
class Within:
    def __init__(self, o):
        self.o = o
    def __lt__(self, other):
        return self.o.within(other.o)
```

As the howto says, the *less than* comparison is guaranteed to be used in sorting. That's what we'll rely on to spatially sort, and the reason why we use `within()` in reverse instead of `contains()`. Trying it out on features *d* and *c*, we see that it works.

```
>>> d < c
True
>>> Within(d) < Within(c)
False
```

It also works on the list of features, producing the order we want.

```
>>> [d, c, c, b, a] == sorted(features, key=Within, reverse=True)
True
```

## DE-9IM Relationships

The `relate()` method tests all the DE-9IM<sup>7</sup> relationships between objects, of which the named relationship predicates above are a subset.

**object.relate(*other*)**

Returns a string representation of the DE-9IM matrix of relationships between an object's *interior*, *boundary*, *exterior* and those of another geometric object.

The named relationship predicates (`contains()`, etc.) are typically implemented as wrappers around `relate()`.

Two different points have mainly F (false) values in their matrix; the intersection of their *external* sets (the 9th element) is a 2 dimensional object (the rest of the plane). The intersection of the *interior* of one with the *exterior* of the other is a 0 dimensional object (3rd and 7th elements of the matrix).

```
>>> Point(0, 0).relate(Point(1, 1))
'FF0FFF0F2'
```

The matrix for a line and a point on the line has more “true” (not F) elements.

```
>>> Point(0, 0).relate(LineString([(0, 0), (1, 1)]))
'F0FFFF102'
```

**object.relate\_pattern(*other*, *pattern*)**

Returns True if the DE-9IM string code for the relationship between the geometries satisfies the pattern, otherwise False.

The `relate_pattern()` compares the DE-9IM code string for two geometries against a specified pattern. If the string matches the pattern then True is returned, otherwise False. The pattern specified can be an exact match (0, 1 or 2), a boolean match (T or F), or a wildcard (\*). For example, the pattern for the *within* predicate is `T*****FF*`.

```
>> point = Point(0.5, 0.5)
>> square = Polygon([(0, 0), (0, 1), (1, 1), (1, 0)])
>> square.relate_pattern(point, 'T*****FF*')
True
>> point.within(square)
True
```

Note that the order of the geometries is significant, as demonstrated below. In this example the square contains the point, but the point does not contain the square.

```
>>> point.relate(square)
'0FFFFFF212'
>>> square.relate(point)
'0F2FF1FF2'
```

Further discussion of the DE-9IM matrix is beyond the scope of this manual. See<sup>7</sup> and <https://pypi.org/project/de9im/>.

## 1.2.4 Spatial Analysis Methods

As well as boolean attributes and methods, Shapely provides analysis methods that return new geometric objects.

### Set-theoretic Methods

Almost every binary predicate method has a counterpart that returns a new geometric object. In addition, the set-theoretic *boundary* of an object is available as a read-only attribute.

**Note:** These methods will *always* return a geometric object. An intersection of disjoint geometries for example will return an empty *GeometryCollection*, not *None* or *False*. To test for a non-empty result, use the geometry's *is\_empty* property.

#### `object.boundary`

Returns a lower dimensional object representing the object's set-theoretic *boundary*.

The boundary of a polygon is a line, the boundary of a line is a collection of points. The boundary of a point is an empty (null) collection.

```
>> coords = [((0, 0), (1, 1)), ((-1, 0), (1, 0))]
>>> lines = MultiLineString(coords)
>>> lines.boundary
<shapely.geometry.multipoint.MultiPoint object at 0x...>
>>> pprint(list(lines.boundary))
[<shapely.geometry.point.Point object at 0x...>,
 <shapely.geometry.point.Point object at 0x...>,
 <shapely.geometry.point.Point object at 0x...>,
 <shapely.geometry.point.Point object at 0x...>]
>>> lines.boundary.boundary
<shapely.geometry.collection.GeometryCollection object at 0x...>
>>> lines.boundary.boundary.is_empty
True
```

See the figures in *LineStrings* and *Collections of Lines* for the illustration of lines and their boundaries.

**object.centroid**

Returns a representation of the object's geometric centroid (point).

```
>>> LineString([(0, 0), (1, 1)]).centroid
<shapely.geometry.point.Point object at 0x...>
>>> LineString([(0, 0), (1, 1)]).centroid.wkt
'POINT (0.5000000000000000 0.5000000000000000)'
```

---

**Note:** The centroid of an object might be one of its points, but this is not guaranteed.

---

**object.difference(*other*)**

Returns a representation of the points making up this geometric object that do not make up the *other* object.

```
>>> a = Point(1, 1).buffer(1.5)
>>> b = Point(2, 1).buffer(1.5)
>>> a.difference(b)
<shapely.geometry.polygon.Polygon object at 0x...>
```

---

**Note:** The `buffer()` method is used to produce approximately circular polygons in the examples of this section; it will be explained in detail later in this manual.

---

Figure 8. Differences between two approximately circular polygons.

---

**Note:** Shapely can not represent the difference between an object and a lower dimensional object (such as the difference between a polygon and a line or point) as a single object, and in these cases the difference method returns a copy of the

---

object named `self`.

**object.intersection(*other*)**

Returns a representation of the intersection of this object with the *other* geometric object.

```
>>> a = Point(1, 1).buffer(1.5)
>>> b = Point(2, 1).buffer(1.5)
>>> a.intersection(b)
<shapely.geometry.polygon.Polygon object at 0x...>
```

See the figure under `symmetric_difference()` below.

**object.symmetric\_difference(*other*)**

Returns a representation of the points in this object not in the *other* geometric object, and the points in the *other* not in this geometric object.

```
>>> a = Point(1, 1).buffer(1.5)
>>> b = Point(2, 1).buffer(1.5)
>>> a.symmetric_difference(b)
<shapely.geometry.multipolygon.MultiPolygon object at ...>
```

**object.union(*other*)**

Returns a representation of the union of points from this object and the *other* geometric object.

The type of object returned depends on the relationship between the operands. The union of polygons (for example) will be a polygon or a multi-polygon depending on whether they intersect or not.

```
>>> a = Point(1, 1).buffer(1.5)
>>> b = Point(2, 1).buffer(1.5)
```

(continues on next page)

(continued from previous page)

```
>>> a.union(b)
<shapely.geometry.polygon.Polygon object at 0x...>
```

The semantics of these operations vary with type of geometric object. For example, compare the boundary of the union of polygons to the union of their boundaries.

```
>>> a.union(b).boundary
<shapely.geometry.polygon.LinearRing object at 0x...>
>>> a.boundary.union(b.boundary)
<shapely.geometry.multilinestring.MultiLineString object at 0x...>
```

---

**Note:** `union()` is an expensive way to find the cumulative union of many objects. See [shapely.ops.unary\\_union\(\)](#) for a more effective method.

---

Several of these set-theoretic methods can be invoked using overloaded operators:

- *intersection* can be accessed with `and`, `&`
- *union* can be accessed with `or`, `|`
- *difference* can be accessed with `minus`, `-`
- *symmetric\_difference* can be accessed with `xor`, `^`

```
>>> from shapely import wkt
>>> p1 = wkt.loads('POLYGON((0 0, 1 0, 1 1, 0 1, 0 0))')
>>> p2 = wkt.loads('POLYGON((0.5 0, 1.5 0, 1.5 1, 0.5 1, 0.5 0))')
>>> (p1 & p2).wkt
'POLYGON ((1 0, 0.5 0, 0.5 1, 1 1, 1 0))'
>>> (p1 | p2).wkt
'POLYGON ((0.5 0, 0 0, 0 1, 0.5 1, 1 1, 1.5 1, 1.5 0, 1 0, 0.5 0))'
>>> (p1 - p2).wkt
'POLYGON ((0.5 0, 0 0, 0 1, 0.5 1, 0.5 0))'
>>> (p1 ^ p2).wkt
'MULTIPOLYGON (((0.5 0, 0 0, 0 1, 0.5 1, 0.5 0)), ((1 0, 1 1, 1.5 1, 1.5 0, 1 0)))'
```

## Constructive Methods

Shapely geometric object have several methods that yield new objects not derived from set-theoretic analysis.

**object.buffer(*distance*, *resolution*=16, *cap\_style*=1, *join\_style*=1, *mitre\_limit*=5.0, *single\_sided*=False)**

Returns an approximate representation of all points within a given *distance* of the this geometric object.

The styles of caps are specified by integer values: 1 (round), 2 (flat), 3 (square). These values are also enumerated by the object [shapely.geometry.CAP\\_STYLE](#) (see below).

The styles of joins between offset segments are specified by integer values: 1 (round), 2 (mitre), and 3 (bevel). These values are also enumerated by the object [shapely.geometry.JOIN\\_STYLE](#) (see below).

**shapely.geometry.CAP\_STYLE**

Attribute	Value
round	1
flat	2
square	3

**shapely.geometry.JOIN\_STYLE**

Attribute	Value
round	1
mitre	2
bevel	3

```
>>> from shapely.geometry import CAP_STYLE, JOIN_STYLE
>>> CAP_STYLE.flat
2
>>> JOIN_STYLE.bevel
3
```

A positive distance has an effect of dilation; a negative distance, erosion. The optional *resolution* argument determines the number of segments used to approximate a quarter circle around a point.

```
>>> line = LineString([(0, 0), (1, 1), (0, 2), (2, 2), (3, 1), (1, 0)])
>>> dilated = line.buffer(0.5)
>>> eroded = dilated.buffer(-0.3)
```

Figure 9. Dilation of a line (left) and erosion of a polygon (right). New object is shown in blue.

The default (*resolution* of 16) buffer of a point is a polygonal patch with 99.8% of the area of the circular disk it approximates.

```
>>> p = Point(0, 0).buffer(10.0)
>>> len(p.exterior.coords)
66
>>> p.area
313.65484905459385
```

With a *resolution* of 1, the buffer is a square patch.

```
>>> q = Point(0, 0).buffer(10.0, 1)
>>> len(q.exterior.coords)
5
>>> q.area
200.0
```

You may want a buffer only on one side. You can achieve this effect with *single\_sided* option.

The side used is determined by the sign of the buffer distance:

- a positive distance indicates the left-hand side
- a negative distance indicates the right-hand side

```
>>> line = LineString([(0, 0), (1, 1), (0, 2), (2, 2), (3, 1), (1, 0)])
>>> left_hand_side = line.buffer(0.5, single_sided=True)
>>> right_hand_side = line.buffer(-0.3, single_sided=True)
```

Figure 10. Single sided buffer of 0.5 left hand (left) and of 0.3 right hand (right).

The single-sided buffer of point geometries is the same as the regular buffer. The End Cap Style for single-sided buffers is always ignored, and forced to the equivalent of `CAP_STYLE.flat`.

Passed a *distance* of 0, `buffer()` can sometimes be used to “clean” self-touching or self-crossing polygons such as the classic “bowtie”. Users have reported that very small distance values sometimes produce cleaner results than 0. Your mileage may vary when cleaning surfaces.

```
>>> coords = [(0, 0), (0, 2), (1, 1), (2, 2), (2, 0), (1, 1), (0, 0)]
>>> bowtie = Polygon(coords)
>>> bowtie.is_valid
False
>>> clean = bowtie.buffer(0)
>>> clean.is_valid
True
>>> clean
<shapely.geometry.multipolygon.MultiPolygon object at ...>
>>> len(clean.geoms)
2
>>> list(clean.geoms[0].exterior.coords)
[(0.0, 0.0), (0.0, 2.0), (1.0, 1.0), (0.0, 0.0)]
>>> list(clean.geoms[1].exterior.coords)
[(1.0, 1.0), (2.0, 2.0), (2.0, 0.0), (1.0, 1.0)]
```

Buffering splits the polygon in two at the point where they touch.

#### `object.convex_hull`

Returns a representation of the smallest convex *Polygon* containing all the points in the object unless the number of points in the object is less than three. For two points, the convex hull collapses to a *LineString*; for 1, a *Point*.

```
>>> Point(0, 0).convex_hull
<shapely.geometry.point.Point object at 0x...>
>>> MultiPoint([(0, 0), (1, 1)]).convex_hull
<shapely.geometry.linestring.LineString object at 0x...>
>>> MultiPoint([(0, 0), (1, 1), (1, -1)]).convex_hull
<shapely.geometry.polygon.Polygon object at 0x...>
```

Figure 11. Convex hull (blue) of 2 points (left) and of 6 points (right).

#### **object.envelope**

Returns a representation of the point or smallest rectangular polygon (with sides parallel to the coordinate axes) that contains the object.

```
>>> Point(0, 0).envelope
<shapely.geometry.point.Point object at 0x...>
>>> MultiPoint([(0, 0), (1, 1)]).envelope
<shapely.geometry.polygon.Polygon object at 0x...>
```

#### **object.minimum\_rotated\_rectangle**

Returns the general minimum bounding rectangle that contains the object. Unlike envelope this rectangle is not constrained to be parallel to the coordinate axes. If the convex hull of the object is a degenerate (line or point) this degenerate is returned.

*New in Shapely 1.6.0*

```
>>> Point(0, 0).minimum_rotated_rectangle
<shapely.geometry.point.Point object at 0x...>
>>> MultiPoint([(0,0),(1,1),(2,0.5)]).minimum_rotated_rectangle
<shapely.geometry.polygon.Polygon object at 0x...>
```

Figure 12. Minimum rotated rectangle for a multipoint feature (left) and a linestring feature (right).

`object.parallel_offset(distance, side, resolution=16, join_style=1, mitre_limit=5.0)`

Returns a `LineString` or `MultiLineString` geometry at a distance from the object on its right or its left side.

The *distance* parameter must be a positive float value.

The *side* parameter may be 'left' or 'right'. Left and right are determined by following the direction of the given geometric points of the `LineString`. Right hand offsets are returned in the reverse direction of the original `LineString` or `LineRing`, while left side offsets flow in the same direction.

The *resolution* of the offset around each vertex of the object is parameterized as in the `buffer()` method.

The *join\_style* is for outside corners between line segments. Accepted integer values are 1 (round), 2 (mitre), and 3 (bevel). See also `shapely.geometry.JOIN_STYLE`.

Severely mitered corners can be controlled by the *mitre\_limit* parameter (spelled in British English, en-gb). The corners of a parallel line will be further from the original than most places with the mitre join style. The ratio of this further distance to the specified *distance* is the miter ratio. Corners with a ratio which exceed the limit will be beveled.

---

**Note:** This method may sometimes return a `MultiLineString` where a simple `LineString` was expected; for example, an offset to a slightly curved `LineString`.

---

---

**Note:** This method is only available for `LinearRing` and `LineString` objects.

---

Figure 13. Three styles of parallel offset lines on the left side of a simple line string (its starting point shown as a circle) and one offset on the right side, a multipart.

The effect of the *mitre\_limit* parameter is shown below.

Figure 14. Large and small *mitre\_limit* values for left and right offsets.

`object.simplify(tolerance, preserve_topology=True)`

Returns a simplified representation of the geometric object.

All points in the simplified object will be within the *tolerance* distance of the original geometry. By default a slower algorithm is used that preserves topology. If *preserve\_topology* is set to `False` the much quicker Douglas-Peucker algorithm<sup>6</sup> is used.

```
>>> p = Point(0.0, 0.0)
>>> x = p.buffer(1.0)
>>> x.area
3.1365484905459389
>>> len(x.exterior.coords)
66
>>> s = x.simplify(0.05, preserve_topology=False)
>>> s.area
3.0614674589207187
>>> len(s.exterior.coords)
17
```

Figure 15. Simplification of a nearly circular polygon using a tolerance of 0.2 (left) and 0.5 (right).

---

**Note:** *Invalid* geometric objects may result from simplification that does not preserve topology and simplification may be sensitive to the order of coordinates: two geometries differing only in order of coordinates may be simplified differently.

---

## 1.2.5 Affine Transformations

A collection of affine transform functions are in the `shapely.affinity` module, which return transformed geometries by either directly supplying coefficients to an affine transformation matrix, or by using a specific, named transform (*rotate*, *scale*, etc.). The functions can be used with all geometry types (except *GeometryCollection*), and 3D types are either preserved or supported by 3D affine transformations.

*New in version 1.2.17.*

`shapely.affinity.affine_transform(geom, matrix)`

Returns a transformed geometry using an affine transformation matrix.

The coefficient *matrix* is provided as a list or tuple with 6 or 12 items for 2D or 3D transformations, respectively.

For 2D affine transformations, the 6 parameter *matrix* is:

`[a, b, d, e, xoff, yoff]`

which represents the augmented matrix:

$$\begin{bmatrix} x' \\ y' \\ 1 \end{bmatrix} = \begin{bmatrix} a & b & x_{\text{off}} \\ d & e & y_{\text{off}} \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} x \\ y \\ 1 \end{bmatrix}$$

---

<sup>6</sup> David H. Douglas and Thomas K. Peucker, "Algorithms for the Reduction of the Number of Points Required to Represent a Digitized Line or its Caricature," *Cartographica: The International Journal for Geographic Information and Geovisualization*, vol. 10, Dec. 1973, pp. 112-122.

or the equations for the transformed coordinates:

$$\begin{aligned}x' &= ax + by + x_{\text{off}} \\ y' &= dx + ey + y_{\text{off}}.\end{aligned}$$

For 3D affine transformations, the 12 parameter `matrix` is:

`[a, b, c, d, e, f, g, h, i, xoff, yoff, zoff]`

which represents the augmented matrix:

$$\begin{bmatrix} x' \\ y' \\ z' \\ 1 \end{bmatrix} = \begin{bmatrix} a & b & c & x_{\text{off}} \\ d & e & f & y_{\text{off}} \\ g & h & i & z_{\text{off}} \\ 0 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} x \\ y \\ z \\ 1 \end{bmatrix}$$

or the equations for the transformed coordinates:

$$\begin{aligned}x' &= ax + by + cz + x_{\text{off}} \\ y' &= dx + ey + fz + y_{\text{off}} \\ z' &= gx + hy + iz + z_{\text{off}}.\end{aligned}$$

`shapely.affinity.rotate(geom, angle, origin='center', use_radians=False)`

Returns a rotated geometry on a 2D plane.

The angle of rotation can be specified in either degrees (default) or radians by setting `use_radians=True`. Positive angles are counter-clockwise and negative are clockwise rotations.

The point of origin can be a keyword `'center'` for the bounding box center (default), `'centroid'` for the geometry's centroid, a *Point* object or a coordinate tuple `(x0, y0)`.

The affine transformation matrix for 2D rotation with angle  $\theta$  is:

$$\begin{bmatrix} \cos \theta & -\sin \theta & x_{\text{off}} \\ \sin \theta & \cos \theta & y_{\text{off}} \\ 0 & 0 & 1 \end{bmatrix}$$

where the offsets are calculated from the origin  $(x_0, y_0)$ :

$$x_{\text{off}} = x_0 - x_0 \cos \theta + y_0 \sin \theta$$

$$y_{\text{off}} = y_0 - x_0 \sin \theta - y_0 \cos \theta$$

```
>>> from shapely import affinity
>>> line = LineString([(1, 3), (1, 1), (4, 1)])
>>> rotated_a = affinity.rotate(line, 90)
>>> rotated_b = affinity.rotate(line, 90, origin='centroid')
```

Figure 16. Rotation of a *LineString* (gray) by an angle of 90° counter-clockwise (blue) using different origins.

`shapely.affinity.scale(geom, xfact=1.0, yfact=1.0, zfact=1.0, origin='center')`

Returns a scaled geometry, scaled by factors along each dimension.

The point of origin can be a keyword `'center'` for the 2D bounding box center (default), `'centroid'` for the geometry's 2D centroid, a *Point* object or a coordinate tuple `(x0, y0, z0)`.

Negative scale factors will mirror or reflect coordinates.

The general 3D affine transformation matrix for scaling is:

$$\begin{bmatrix} x_{\text{fact}} & 0 & 0 & x_{\text{off}} \\ 0 & y_{\text{fact}} & 0 & y_{\text{off}} \\ 0 & 0 & z_{\text{fact}} & z_{\text{off}} \\ 0 & 0 & 0 & 1 \end{bmatrix}$$

where the offsets are calculated from the origin  $(x_0, y_0, z_0)$ :

$$x_{\text{off}} = x_0 - x_0 x_{\text{fact}}$$

$$y_{\text{off}} = y_0 - y_0 y_{\text{fact}}$$

$$z_{\text{off}} = z_0 - z_0 z_{\text{fact}}$$

```
>>> triangle = Polygon([(1, 1), (2, 3), (3, 1)])
>>> triangle_a = affinity.scale(triangle, xfact=1.5, yfact=-1)
>>> triangle_a.exterior.coords[:]
[(-0.5, 3.0), (2.0, 1.0), (3.5, 3.0), (-0.5, 3.0)]
>>> triangle_b = affinity.scale(triangle, xfact=2, origin=(1,1))
>>> triangle_b.exterior.coords[:]
[(1.0, 1.0), (3.0, 3.0), (5.0, 1.0), (1.0, 1.0)]
```

Figure 17. Scaling of a gray triangle to blue result: a) by a factor of 1.5 along x-direction, with reflection across y-axis; b) by a factor of 2 along x-direction with custom origin at (1, 1).

`shapely.affinity.skew(geom, xs=0.0, ys=0.0, origin='center', use_radians=False)`

Returns a skewed geometry, sheared by angles along x and y dimensions.

The shear angle can be specified in either degrees (default) or radians by setting `use_radians=True`.

The point of origin can be a keyword 'center' for the bounding box center (default), 'centroid' for the geometry's centroid, a *Point* object or a coordinate tuple `(x0, y0)`.

The general 2D affine transformation matrix for skewing is:

$$\begin{bmatrix} 1 & \tan x_s & x_{\text{off}} \\ \tan y_s & 1 & y_{\text{off}} \\ 0 & 0 & 1 \end{bmatrix}$$

where the offsets are calculated from the origin  $(x_0, y_0)$ :

$$x_{\text{off}} = -y_0 \tan x_s$$

$$y_{\text{off}} = -x_0 \tan y_s$$

Figure 18. Skewing of a gray “R” to blue result: a) by a shear angle of 20° along the x-direction and an origin at (1, 1); b) by a shear angle of 30° along the y-direction, using default origin.

`shapely.affinity.translate(geom, xoff=0.0, yoff=0.0, zoff=0.0)`

Returns a translated geometry shifted by offsets along each dimension.

The general 3D affine transformation matrix for translation is:

$$\begin{bmatrix} 1 & 0 & 0 & x_{\text{off}} \\ 0 & 1 & 0 & y_{\text{off}} \\ 0 & 0 & 1 & z_{\text{off}} \\ 0 & 0 & 0 & 1 \end{bmatrix}$$

## 1.2.6 Other Transformations

Shapely supports map projections and other arbitrary transformations of geometric objects.

`shapely.ops.transform(func, geom)`

Applies *func* to all coordinates of *geom* and returns a new geometry of the same type from the transformed coordinates.

*func* maps x, y, and optionally z to output xp, yp, zp. The input parameters may be iterable types like lists or arrays or single values. The output shall be of the same type: scalars in, scalars out; lists in, lists out.

*transform* tries to determine which kind of function was passed in by calling *func* first with *n* iterables of coordinates, where *n* is the dimensionality of the input geometry. If *func* raises a *TypeError* when called with iterables as arguments, then it will instead call *func* on each individual coordinate in the geometry.

*New in version 1.2.18.*

For example, here is an identity function applicable to both types of input (scalar or array).

```
def id_func(x, y, z=None):
    return tuple(filter(None, [x, y, z]))

g2 = transform(id_func, g1)
```

If using *pyproj* ≥ 2.1.0, the preferred method to project geometries is:

```
import pyproj

from shapely.geometry import Point
from shapely.ops import transform

wgs84_pt = Point(-72.2495, 43.886)

wgs84 = pyproj.CRS('EPSG:4326')
utm = pyproj.CRS('EPSG:32618')

project = pyproj.Transformer.from_crs(wgs84, utm, always_xy=True).transform
utm_point = transform(project, wgs84_pt)
```

It is important to note that in the example above, the *always\_xy* kwarg is required as Shapely only supports coordinates in X,Y order, and in PROJ 6 the WGS84 CRS uses the EPSG-defined Lat/Lon coordinate order instead of the expected Lon/Lat.

If using *pyproj* < 2.1, then the canonical example is:

```
from functools import partial
import pyproj

from shapely.ops import transform

wgs84 = pyproj.Proj(init='epsg:4326')
utm = pyproj.Proj(init='epsg:32618')

project = partial(
    pyproj.transform,
    wgs84,
    utm)

utm_point = transform(project, wgs84_pt)
```

Lambda expressions such as the one in

```
g2 = transform(lambda x, y, z=None: (x+1.0, y+1.0), g1)
```

also satisfy the requirements for *func*.

## 1.2.7 Other Operations

### Merging Linear Features

Sequences of touching lines can be merged into *MultiLineStrings* or *Polygons* using functions in the `shapely.ops` module.

`shapely.ops.polygonize(lines)`

Returns an iterator over polygons constructed from the input *lines*.

As with the *MultiLineString* constructor, the input elements may be any line-like object.

```
>>> from shapely.ops import polygonize
>>> lines = [
...     ((0, 0), (1, 1)),
...     ((0, 0), (0, 1)),
...     ((0, 1), (1, 1)),
...     ((1, 1), (1, 0)),
...     ((1, 0), (0, 0))
... ]
>>> pprint(list(polygonize(lines)))
[<shapely.geometry.polygon.Polygon object at 0x...>,
 <shapely.geometry.polygon.Polygon object at 0x...>]
```

`shapely.ops.polygonize_full(lines)`

Creates polygons from a source of lines, returning the polygons and leftover geometries.

The source may be a *MultiLineString*, a sequence of *LineString* objects, or a sequence of objects than can be adapted to *LineStrings*.

Returns a tuple of objects: (polygons, dangles, cut edges, invalid ring lines). Each are a geometry collection.

Dangles are edges which have one or both ends which are not incident on another edge endpoint. Cut edges are connected at both ends but do not form part of polygon. Invalid ring lines form rings which are invalid (bowties, etc).

*New in version 1.2.18.*

```
>>> lines = [
...     ((0, 0), (1, 1)),
...     ((0, 0), (0, 1)),
...     ((0, 1), (1, 1)),
...     ((1, 1), (1, 0)),
...     ((1, 0), (0, 0)),
...     ((5, 5), (6, 6)),
...     ((1, 1), (100, 100)),
... ]
>>> result, dangles, cuts, invalids = polygonize_full(lines)
>>> len(result.geoms)
2
>>> list(result.geoms)
[<shapely.geometry.polygon.Polygon object at ...>, <shapely.geometry.polygon.
↳ Polygon object at ...>]
>>> list(cuts.geoms)
[<shapely.geometry.linestring.LineString object at ...>, <shapely.geometry.
↳ linestring.LineString object at ...>]
```

`shapely.ops.linemerge(lines)`

Returns a *LineString* or *MultiLineString* representing the merger of all contiguous elements of *lines*.

As with `shapely.ops.polygonize()`, the input elements may be any line-like object.

```
>>> from shapely.ops import linemerge
>>> linemerge(lines)
<shapely.geometry.multilinestring.MultiLineString object at 0x...>
>>> pprint(list(linemerge(lines)))
[<shapely.geometry.linestring.LineString object at 0x...>,
 <shapely.geometry.linestring.LineString object at 0x...>,
 <shapely.geometry.linestring.LineString object at 0x...>]
```

## Efficient Rectangle Clipping

The `clip_by_rect()` function in *shapely.ops* returns the portion of a geometry within a rectangle.

`shapely.ops.clip_by_rect(geom, xmin, ymin, xmax, ymax)`

The geometry is clipped in a fast but possibly dirty way. The output is not guaranteed to be valid. No exceptions will be raised for topological errors.

*New in version 1.7.*

Requires GEOS 3.5.0 or higher

```
>>> from shapely.geometry import Polygon
>>> from shapely.ops import clip_by_rect
>>> polygon = Polygon(
    shell=[(0, 0), (0, 30), (30, 30), (30, 0), (0, 0)],
    holes=[[ (10, 10), (20, 10), (20, 20), (10, 20), (10, 10) ]],
)
>>> clipped_polygon = clip_by_rect(polygon, 5, 5, 15, 15)
>>> print(clipped_polygon.wkt)
POLYGON ((5 5, 5 15, 10 15, 10 10, 15 10, 15 5, 5 5))
```

## Efficient Unions

The `unary_union()` function in *shapely.ops* is more efficient than accumulating with `union()`.

`shapely.ops.unary_union(geoms)`

Returns a representation of the union of the given geometric objects.

Areas of overlapping *Polygons* will get merged. *LineStrings* will get fully dissolved and noded. Duplicate *Points* will get merged.

```
>>> from shapely.ops import unary_union
>>> polygons = [Point(i, 0).buffer(0.7) for i in range(5)]
>>> unary_union(polygons)
<shapely.geometry.polygon.Polygon object at 0x...>
```

Because the union merges the areas of overlapping *Polygons* it can be used in an attempt to fix invalid *MultiPolygons*. As with the zero distance `buffer()` trick, your mileage may vary when using this.

```
>>> m = MultiPolygon(polygons)
>>> m.area
7.6845438018375516
>>> m.is_valid
False
>>> unary_union(m).area
6.6103013551167971
>>> unary_union(m).is_valid
True
```

`shapely.ops.cascaded_union(geoms)`

Returns a representation of the union of the given geometric objects.

---

**Note:** In 1.8.0 `shapely.ops.cascaded_union()` is deprecated, as it was superseded by `shapely.ops.unary_union()`.

---

## Delaunay triangulation

The `triangulate()` function in `shapely.ops` calculates a Delaunay triangulation from a collection of points.

`shapely.ops.triangulate(geom, tolerance=0.0, edges=False)`

Returns a Delaunay triangulation of the vertices of the input geometry.

The source may be any geometry type. All vertices of the geometry will be used as the points of the triangulation.

The `tolerance` keyword argument sets the snapping tolerance used to improve the robustness of the triangulation computation. A tolerance of 0.0 specifies that no snapping will take place.

If the `edges` keyword argument is `False` a list of *Polygon* triangles will be returned. Otherwise a list of *LineString* edges is returned.

*New in version 1.4.0*

```
>>> from shapely.ops import triangulate
>>> points = MultiPoint([(0, 0), (1, 1), (0, 2), (2, 2), (3, 1), (1, 0)])
>>> triangles = triangulate(points)
>>> pprint([triangle.wkt for triangle in triangles])
['POLYGON ((0 2, 0 0, 1 1, 0 2))',
 'POLYGON ((0 2, 1 1, 2 2, 0 2))',
 'POLYGON ((2 2, 1 1, 3 1, 2 2))',
 'POLYGON ((3 1, 1 1, 1 0, 3 1))',
 'POLYGON ((1 0, 1 1, 0 0, 1 0))']
```

## Voronoi Diagram

The `voronoi_diagram()` function in `shapely.ops` constructs a Voronoi diagram from a collection points, or the vertices of any geometry.

`shapely.ops.voronoi_diagram(geom, envelope=None, tolerance=0.0, edges=False)`

Constructs a Voronoi diagram from the vertices of the input geometry.

The source may be any geometry type. All vertices of the geometry will be used as the input points to the diagram.

The `envelope` keyword argument provides an envelope to use to clip the resulting diagram. If `None`, it will be calculated automatically. The diagram will be clipped to the *larger* of the provided envelope or an envelope surrounding the sites.

The `tolerance` keyword argument sets the snapping tolerance used to improve the robustness of the computation. A tolerance of 0.0 specifies that no snapping will take place. The tolerance *argument* can be finicky and is known to cause the algorithm to fail in several cases. If you're using `tolerance` and getting a failure, try removing it. The test cases in `tests/test_voronoi_diagram.py` show more details.

If the `edges` keyword argument is `False` a list of `Polygon`'s will be returned. Otherwise a list of `LineString` edges is returned.

```
>>> from shapely.ops import voronoi_diagram
>>> points = MultiPoint([(0, 0), (1, 1), (0, 2), (2, 2), (3, 1), (1, 0)])
>>> regions = voronoi_diagram(points)
>>> pprint([region.wkt for region in regions])
['POLYGON ((2 1, 2 0.5, 0.5 0.5, 0 1, 1 2, 2 1))',
 'POLYGON ((6 5, 6 -3, 3.75 -3, 2 0.5, 2 1, 6 5))',
 'POLYGON ((0.5 -3, -3 -3, -3 1, 0 1, 0.5 0.5, 0.5 -3))',
 'POLYGON ((3.75 -3, 0.5 -3, 0.5 0.5, 2 0.5, 3.75 -3))',
```

(continues on next page)

(continued from previous page)

```
'POLYGON ((-3 1, -3 5, 1 5, 1 2, 0 1, -3 1))',
'POLYGON ((1 5, 6 5, 2 1, 1 2, 1 5))']
```

## Nearest points

The `nearest_points()` function in `shapely.ops` calculates the nearest points in a pair of geometries.

`shapely.ops.nearest_points(geom1, geom2)`

Returns a tuple of the nearest points in the input geometries. The points are returned in the same order as the input geometries.

*New in version 1.4.0.*

```
>>> from shapely.ops import nearest_points
>>> triangle = Polygon([(0, 0), (1, 0), (0.5, 1), (0, 0)])
>>> square = Polygon([(0, 2), (1, 2), (1, 3), (0, 3), (0, 2)])
>>> [o.wkt for o in nearest_points(triangle, square)]
['POINT (0.5 1)', 'POINT (0.5 2)']
```

Note that the nearest points may not be existing vertices in the geometries.

## Snapping

The `snap()` function in `shapely.ops` snaps the vertices in one geometry to the vertices in a second geometry with a given tolerance.

`shapely.ops.snap(geom1, geom2, tolerance)`

Snaps vertices in `geom1` to vertices in the `geom2`. A copy of the snapped geometry is returned. The input geometries are not modified.

The `tolerance` argument specifies the minimum distance between vertices for them to be snapped.

*New in version 1.5.0*

```
>>> from shapely.ops import snap
>>> square = Polygon([(1,1), (2, 1), (2, 2), (1, 2), (1, 1)])
>>> line = LineString([(0,0), (0.8, 0.8), (1.8, 0.95), (2.6, 0.5)])
>>> result = snap(line, square, 0.5)
>>> result.wkt
'LINESTRING (0 0, 1 1, 2 1, 2.6 0.5)'
```

## Shared paths

The `shared_paths()` function in `shapely.ops` finds the shared paths between two linear geometries.

`shapely.ops.shared_paths(geom1, geom2)`

Finds the shared paths between `geom1` and `geom2`, where both geometries are *LineStrings*.

A *GeometryCollection* is returned with two elements. The first element is a *MultiLineString* containing shared paths with the same direction for both inputs. The second element is a *MultiLineString* containing shared paths with the opposite direction for the two inputs.

*New in version 1.6.0*

```
>>> from shapely.ops import shared_paths
>>> g1 = LineString([(0, 0), (10, 0), (10, 5), (20, 5)])
>>> g2 = LineString([(5, 0), (30, 0), (30, 5), (0, 5)])
>>> forward, backward = shared_paths(g1, g2)
>>> forward.wkt
'MULTILINESTRING ((5 0, 10 0))'
>>> backward.wkt
'MULTILINESTRING ((10 5, 20 5))'
```

## Splitting

The `split()` function in `shapely.ops` splits a geometry by another geometry.

`shapely.ops.split(geom, splitter)`

Splits a geometry by another geometry and returns a collection of geometries. This function is the theoretical opposite of the union of the split geometry parts. If the splitter does not split the geometry, a collection with a single geometry equal to the input geometry is returned.

The function supports:

- Splitting a (Multi)LineString by a (Multi)Point or (Multi)LineString or (Multi)Polygon boundary
- Splitting a (Multi)Polygon by a LineString

It may be convenient to snap the splitter with low tolerance to the geometry. For example in the case of splitting a line by a point, the point must be exactly on the line, for the line to be correctly split. When splitting a line by a polygon, the boundary of the polygon is used for the operation. When splitting a line by another line, a `ValueError` is raised if the two overlap at some segment.

*New in version 1.6.0*

```
>>> pt = Point((1, 1))
>>> line = LineString([(0,0), (2,2)])
>>> result = split(line, pt)
>>> result.wkt
'GEOMETRYCOLLECTION (LINESTRING (0 0, 1 1), LINESTRING (1 1, 2 2))'
```

## Substring

The `substring()` function in `shapely.ops` returns a line segment between specified distances along a *LineString*.

`shapely.ops.substring(geom, start_dist, end_dist[, normalized=False])`

Return the *LineString* between *start\_dist* and *end\_dist* or a *Point* if they are at the same location

Negative distance values are taken as measured in the reverse direction from the end of the geometry. Out-of-range index values are handled by clamping them to the valid range of values.

If the start distance equals the end distance, a point is being returned.

If the start distance is actually past the end distance, then the reversed substring is returned such that the start distance is at the first coordinate.

If the normalized arg is `True`, the distance will be interpreted as a fraction of the geometry's length

*New in version 1.7.0*

Here are some examples that return *LineString* geometries.

```
>>> from shapely.geometry import LineString
>>> from shapely.ops import substring
>>> ls = LineString((i, 0) for i in range(6))
>>> ls.wkt
'LINESTRING (0 0, 1 0, 2 0, 3 0, 4 0, 5 0)'
>>> substring(ls, start_dist=1, end_dist=3).wkt
'LINESTRING (1 0, 2 0, 3 0)'
>>> substring(ls, start_dist=3, end_dist=1).wkt
'LINESTRING (3 0, 2 0, 1 0)'
>>> substring(ls, start_dist=1, end_dist=-3).wkt
'LINESTRING (1 0, 2 0)'
>>> substring(ls, start_dist=0.2, end_dist=-0.6, normalized=True).wkt
'LINESTRING (1 0, 2 0)'
```

And here is an example that returns a *Point*.

```
>>> substring(ls, start_dist=2.5, end_dist=-2.5)
'POINT (2.5 0)'
```

## Prepared Geometry Operations

Shapely geometries can be processed into a state that supports more efficient batches of operations.

**prepared.prep(*ob*)**

Creates and returns a prepared geometric object.

To test one polygon containment against a large batch of points, one should first use the *prepared.prep()* function.

```
>>> from shapely.geometry import Point
>>> from shapely.prepared import prep
>>> points = [...] # large list of points
>>> polygon = Point(0.0, 0.0).buffer(1.0)
>>> prepared_polygon = prep(polygon)
>>> prepared_polygon
<shapely.prepared.PreparedGeometry object at 0x...>
>>> hits = filter(prepared_polygon.contains, points)
```

Prepared geometries instances have the following methods: `contains`, `contains_properly`, `covers`, and `intersects`. All have exactly the same arguments and usage as their counterparts in non-prepared geometric objects.

## Diagnostics

**validation.explain\_validity(*ob*):**

Returns a string explaining the validity or invalidity of the object.

*New in version 1.2.1.*

The messages may or may not have a representation of a problem point that can be parsed out.

```
>>> coords = [(0, 0), (0, 2), (1, 1), (2, 2), (2, 0), (1, 1), (0, 0)]
>>> p = Polygon(coords)
>>> from shapely.validation import explain_validity
```

(continues on next page)

(continued from previous page)

```
>>> explain_validity(p)
'Ring Self-intersection[1 1]'
```

`validation.make_valid(ob)`

Returns a valid representation of the geometry, if it is invalid. If it is valid, the input geometry will be returned.

In many cases, in order to create a valid geometry, the input geometry must be split into multiple parts or multiple geometries. If the geometry must be split into multiple parts of the same geometry type, then a multi-part geometry (e.g. a MultiPolygon) will be returned. If the geometry must be split into multiple parts of different types, then a GeometryCollection will be returned.

For example, this operation on a geometry with a bow-tie structure:

```
>>> from shapely.validation import make_valid
>>> coords = [(0, 0), (0, 2), (1, 1), (2, 2), (2, 0), (1, 1), (0, 0)]
>>> p = Polygon(coords)
>>> str(make_valid(p))
'MULTIPOLYGON (((0 0, 0 2, 1 1, 0 0)), ((1 1, 2 2, 2 0, 1 1)))'
```

Yields a MultiPolygon with two parts:

Fig. 1: While this operation:

```
>>> from shapely.validation import make_valid
>>> coords = [(0, 2), (0, 1), (2, 0), (0, 0), (0, 2)]
>>> p = Polygon(coords)
>>> str(make_valid(p))
```

(continues on next page)

(continued from previous page)

Yields a GeometryCollection with a Polygon and a LineString:

The Shapely version, GEOS library version, and GEOS C API version are accessible via `shapely.__version__`, `shapely.geos.geos_version_string`, and `shapely.geos.geos_capi_version`.

```
>>> import shapely
>>> shapely.__version__
'1.3.0'
>>> import shapely.geos
>>> shapely.geos.geos_version
(3, 3, 0)
>>> shapely.geos.geos_version_string
'3.3.0-CAPI-1.7.0'
```

## Polylabel

`shapely.ops.polylabel`(*polygon*, *tolerance*)

Finds the approximate location of the pole of inaccessibility for a given polygon. Based on Vladimir Agafonkin's [polylabel](#).

*New in version 1.6.0*

---

**Note:** Prior to 1.7 `polylabel` must be imported from `shapely.algorithms.polylabel` instead of `shapely.ops`.

---

```
>>> from shapely.ops import polylabel
>>> polygon = LineString([(0, 0), (50, 200), (100, 100), (20, 50),
... (-100, -20), (-150, -200)]).buffer(100)
>>> label = polylabel(polygon, tolerance=10)
>>> label.wkt
'POINT (59.35615556364569 121.8391962974644)'
```

## 1.2.8 STR-packed R-tree

Shapely provides an interface to the query-only GEOS R-tree packed using the Sort-Tile-Recursive algorithm. Pass a list of geometry objects to the `STRtree` constructor to create a spatial index that you can query with another geometric object. Query-only means that once created, the *STRtree* is immutable. You cannot add or remove geometries.

**class** `strtree.STRtree`(*geometries*)

The *STRtree* constructor takes a sequence of geometric objects.

References to these geometric objects are kept and stored in the R-tree.

*New in version 1.4.0.*

`strtree.query`(*geom*)

Returns a list of all geometries in the *strtree* whose extents intersect the extent of *geom*. This means that a subsequent search through the returned subset using the desired binary predicate (eg. intersects, crosses, contains, overlaps) may be necessary to further filter the results according to their specific spatial relationships.

```
>>> from shapely.strtree import STRtree
>>> points = [Point(i, i) for i in range(10)]
>>> tree = STRtree(points)
>>> query_geom = Point(2,2).buffer(0.99)
>>> [o.wkt for o in tree.query(query_geom)]
['POINT (2 2)']
>>> query_geom = Point(2, 2).buffer(1.0)
>>> [o.wkt for o in tree.query(query_geom)]
['POINT (1 1)', 'POINT (2 2)', 'POINT (3 3)']
>>> [o.wkt for o in tree.query(query_geom) if o.intersects(query_geom)]
['POINT (2 2)']
```

---

**Note:** To get the original indexes of the query results, create an auxiliary dictionary. But use the geometry *ids* as keys since the shapely geometries themselves are not hashable.

```
>>> index_by_id = dict((id(pt), i) for i, pt in enumerate(points))
>>> [(index_by_id[id(pt)], pt.wkt) for pt in tree.query(Point(2,2).buffer(1.0))]
[(1, 'POINT (1 1)'), (2, 'POINT (2 2)'), (3, 'POINT (3 3)')]
```

`strtree.nearest`(*geom*)

Returns the nearest geometry in *strtree* to *geom*.

```
>>> tree = STRtree([Point(i, i) for i in range(10)])
>>> tree.nearest(Point(2.2, 2.2)).wkt
'Point (2 2)'
```

## 1.2.9 Interoperation

Shapely provides 4 avenues for interoperation with other software.

### Well-Known Formats

A *Well Known Text* (WKT) or *Well Known Binary* (WKB) representation<sup>?</sup> of any geometric object can be had via its `wkt` or `wkb` attribute. These representations allow interchange with many GIS programs. PostGIS, for example, trades in hex-encoded WKB.

```
>>> Point(0, 0).wkt
'POINT (0.0000000000000000 0.0000000000000000)'
>>> Point(0, 0).wkb.encode('hex')
'0101000000000000000000000000000000000000000000000000'
```

The `shapely.wkt` and `shapely.wkb` modules provide `dumps()` and `loads()` functions that work almost exactly as their `pickle` and `simplejson` module counterparts. To serialize a geometric object to a binary or text string, use `dumps()`. To deserialize a string and get a new geometric object of the appropriate type, use `loads()`.

The default settings for the `wkt` attribute and `shapely.wkt.dumps()` function are different. By default, the attribute's value is trimmed of excess decimals, while this is not the case for `dumps()`, though it can be replicated by setting `trim=True`.

`shapely.wkb.dumps(ob)`

Returns a WKB representation of *ob*.

`shapely.wkb.loads(wkb)`

Returns a geometric object from a WKB representation *wkb*.

```
>>> from shapely import wkb
>>> pt = Point(0, 0)
>>> wkb.dumps(pt)
b'\x01\x01\x00\x00\x00\x00\x00\x00\x00\x00\x00\x00\x00\x00\x00\x00\x00\x00\x00\x00'
>>> pt.wkb
b'\x01\x01\x00\x00\x00\x00\x00\x00\x00\x00\x00\x00\x00\x00\x00\x00\x00\x00\x00\x00'
>>> pt.wkb_hex
'0101000000000000000000000000000000000000000000000000'
>>> wkb.loads(pt.wkb).wkt
'POINT (0 0)'
```

All of Shapely's geometry types are supported by these functions.

`shapely.wkt.dumps(ob)`

Returns a WKT representation of *ob*. Several keyword arguments are available to alter the WKT which is returned; see the docstrings for more details.

`shapely.wkt.loads(wkt)`

Returns a geometric object from a WKT representation *wkt*.

```
>>> from shapely import wkt
>>> pt = Point(0, 0)
>>> thewkt = wkt.dumps(pt)
>>> thewkt
'POINT (0.0000000000000000 0.0000000000000000)'
>>> pt.wkt
'POINT (0 0)'
```

(continues on next page)

(continued from previous page)

```
>>> wkt.dumps(pt, trim=True)
'POINT (0 0)'
```

## Numpy and Python Arrays

All geometric objects with coordinate sequences (*Point*, *LinearRing*, *LineString*) provide the Numpy array interface and can thereby be converted or adapted to Numpy arrays.

```
>>> from numpy import asarray
>>> asarray(Point(0, 0))
array([ 0.,  0.])
>>> asarray(LineString([(0, 0), (1, 1)]))
array([[ 0.,  0.],
       [ 1.,  1.]])
```

---

**Note:** The Numpy array interface is provided without a dependency on Numpy itself.

---

The coordinates of the same types of geometric objects can be had as standard Python arrays of *x* and *y* values via the *xy* attribute.

```
>>> Point(0, 0).xy
(array('d', [0.0]), array('d', [0.0]))
>>> LineString([(0, 0), (1, 1)]).xy
(array('d', [0.0, 1.0]), array('d', [0.0, 1.0]))
```

The *shapely.geometry.asShape()* family of functions can be used to wrap Numpy coordinate arrays so that they can then be analyzed using Shapely while maintaining their original storage. A 1 x 2 array can be adapted to a point

```
>>> from shapely.geometry import asPoint
>>> pa = asPoint(array([0.0, 0.0]))
>>> pa.wkt
'POINT (0.0000000000000000 0.0000000000000000)'
```

and a N x 2 array can be adapted to a line string

```
>>> from shapely.geometry import asLineString
>>> la = asLineString(array([[1.0, 2.0], [3.0, 4.0]]))
>>> la.wkt
'LINESTRING (1.0000000000000000 2.0000000000000000, 3.0000000000000000 4.
↪ 0000000000000000)'
```

Polygon and MultiPoint can also be created from N x 2 arrays:

```
>>> from shapely.geometry import asMultiPoint
>>> ma = asMultiPoint(np.array([[1.1, 2.2], [3.3, 4.4], [5.5, 6.6]]))
>>> ma.wkt
'MULTIPOINT (1.1 2.2, 3.3 4.4, 5.5 6.6)'
```

```
>>> from shapely.geometry import asPolygon
>>> pa = asPolygon(np.array([[1.1, 2.2], [3.3, 4.4], [5.5, 6.6]]))
```

(continues on next page)

(continued from previous page)

```
>>> pa.wkt
'POLYGON ((1.1 2.2, 3.3 4.4, 5.5 6.6, 1.1 2.2))'
```

## Python Geo Interface

Any object that provides the GeoJSON-like [Python geo interface](#) can be adapted and used as a Shapely geometry using the `shapely.geometry.asShape()` or `shapely.geometry.shape()` functions.

`shapely.geometry.asShape(context)`

Adapts the context to a geometry interface. The coordinates remain stored in the context.

`shapely.geometry.shape(context)`

Returns a new, independent geometry with coordinates *copied* from the context.

For example, a dictionary:

```
>>> from shapely.geometry import shape
>>> data = {"type": "Point", "coordinates": (0.0, 0.0)}
>>> geom = shape(data)
>>> geom.geom_type
'Point'
>>> list(geom.coords)
[(0.0, 0.0)]
```

Or a simple placemark-type object:

```
>>> class GeoThing:
...     def __init__(self, d):
...         self.__geo_interface__ = d
>>> thing = GeoThing({"type": "Point", "coordinates": (0.0, 0.0)})
>>> geom = shape(thing)
>>> geom.geom_type
'Point'
>>> list(geom.coords)
[(0.0, 0.0)]
```

The GeoJSON-like mapping of a geometric object can be obtained using `shapely.geometry.mapping()`.

`shapely.geometry.mapping(ob)`

Returns a new, independent geometry with coordinates *copied* from the context.

*New in version 1.2.3.*

For example, using the same *GeoThing* class:

```
>>> from shapely.geometry import mapping
>>> thing = GeoThing({"type": "Point", "coordinates": (0.0, 0.0)})
>>> m = mapping(thing)
>>> m['type']
'Point'
>>> m['coordinates']
(0.0, 0.0)
```

### 1.2.10 Performance

Shapely uses the [GEOS](#) library for all operations. GEOS is written in C++ and used in many applications and you can expect that all operations are highly optimized. The creation of new geometries with many coordinates, however, involves some overhead that might slow down your code.

New in version 1.2.10.

The `shapely.speedups` module contains performance enhancements written in C. They are automatically installed when Python has access to a compiler and GEOS development headers during installation.

You can check if the speedups are installed with the `available` attribute. To enable the speedups call `enable()`. You can revert to the slow implementation with `disable()`.

```
>>> from shapely import speedups
>>> speedups.available
True
>>> speedups.enable()
```

New in version 1.6.0.

Speedups are now enabled by default if they are available. You can check if speedups are enabled with the `enabled` attribute.

```
>>> from shapely import speedups
>>> speedups.enabled
True
```

### 1.2.11 Conclusion

We hope that you will enjoy and profit from using Shapely. This manual will be updated and improved regularly. Its source is available at <https://github.com/Toblerity/Shapely/tree/master/docs/>.

### 1.2.12 References

## 1.3 Migrating to Shapely 1.8 / 2.0

Shapely 1.8.0 is a transitional version introducing several warnings in preparation of the upcoming changes in 2.0.0.

Shapely 2.0.0 will be a major release with a refactor of the internals with considerable performance improvements (based on the developments in the [PyGEOS](#) package), along with several breaking changes.

This guide gives an overview of the most important changes with details on what will change in 2.0.0, how we warn for this in 1.8.0, and how you can update your code to be future-proof.

For more background, see [RFC 1: Roadmap for Shapely 2.0](#).

#### Table of Contents

- *Geometry objects will become immutable*
  - *Setting custom attributes*
- *Multi-part geometries will no longer be “sequences” (length, iterable, indexable)*

- *Interoperability with NumPy and the array interface*
  - *Conversion of the coordinates to (NumPy) arrays*
  - *Creating NumPy arrays of geometry objects*
- *Consistent creation of empty geometries*
- *Other deprecated functionality*

### 1.3.1 Geometry objects will become immutable

Geometry objects will become immutable in version 2.0.0.

In Shapely 1.x, some of the geometry classes are mutable, meaning that you can change their coordinates in-place. Illustrative code:

```
>>> from shapely.geometry import LineString
>>> line = LineString([(0,0), (2, 2)])
>>> print(line)
LINESTRING (0 0, 2 2)

>>> line.coords = [(0, 0), (10, 0), (10, 10)]
>>> print(line)
LINESTRING (0 0, 10 0, 10 10)
```

In Shapely 1.8, this will start raising a warning:

```
>>> line.coords = [(0, 0), (10, 0), (10, 10)]
ShapelyDeprecationWarning: Setting the 'coords' to mutate a Geometry
in place is deprecated, and will not be possible any more in Shapely 2.0
```

and starting with version 2.0.0, all geometry objects will become immutable. As a consequence, they will also become hashable and therefore usable as, for example, dictionary keys.

**How do I update my code?** There is no direct alternative for mutating the coordinates of an existing geometry, except for creating a new geometry object with the new coordinates.

#### Setting custom attributes

Another consequence of the geometry objects becoming immutable is that assigning custom attributes, which currently works, will no longer be possible.

Currently you can do:

```
>>> line.name = "my_geometry"
>>> line.name
'my_geometry'
```

In Shapely 1.8, this will start raising a warning, and will raise an `AttributeError` in Shapely 2.0.

**How do I update my code?** There is no direct alternative for adding custom attributes to geometry objects. You can use other Python data structures such as (GeoJSON-like) dictionaries or GeoPandas' `GeoDataFrames` to store attributes alongside geometry features.

### 1.3.2 Multi-part geometries will no longer be “sequences” (length, iterable, indexable)

In Shapely 1.x, multi-part geometries (MultiPoint, MultiLineString, MultiPolygon and GeometryCollection) implement a part of the “sequence” python interface (making them list-like). This means you can iterate through the object to get the parts, index into the object to get a specific part, and ask for the number of parts with the `len()` method.

Some examples of this with Shapely 1.x:

```
>>> from shapely.geometry import Point, MultiPoint
>>> mp = MultiPoint([(1, 1), (2, 2), (3, 3)])
>>> print(mp)
MULTIPOINT (1 1, 2 2, 3 3)
>>> for part in mp:
...     print(part)
POINT (1 1)
POINT (2 2)
POINT (3 3)
>>> print(mp[1])
POINT (2 2)
>>> len(mp)
3
>>> list(mp)
[<shapely.geometry.point.Point at 0x7f2e0912bf10>,
 <shapely.geometry.point.Point at 0x7f2e09fed820>,
 <shapely.geometry.point.Point at 0x7f2e09fed4c0>]
```

Starting with Shapely 1.8, all the examples above will start raising a deprecation warning. For example:

```
>>> for part in mp:
...     print(part)
ShapelyDeprecationWarning: Iteration over multi-part geometries is deprecated
and will be removed in Shapely 2.0. Use the `geoms` property to access the
constituent parts of a multi-part geometry.
POINT (1 1)
POINT (2 2)
POINT (3 3)
```

In Shapely 2.0, all those examples will raise an error.

**How do I update my code?** To access the geometry parts of a multi-part geometry, you can use the `.geoms` attribute, as the warning indicates.

The examples above can be updated to:

```
>>> for part in mp.geoms:
...     print(part)
POINT (1 1)
POINT (2 2)
POINT (3 3)
>>> print(mp.geoms[1])
POINT (2 2)
>>> len(mp.geoms)
3
>>> list(mp.geoms)
```

(continues on next page)

(continued from previous page)

```
[<shapely.geometry.point.Point at 0x7f2e0912bf10>,
 <shapely.geometry.point.Point at 0x7f2e09fed820>,
 <shapely.geometry.point.Point at 0x7f2e09fed4c0>]
```

The single-part geometries (Point, LineString, Polygon) already didn't support those features, and for those classes there is no change in behaviour for this aspect.

### 1.3.3 Interoperability with NumPy and the array interface

#### Conversion of the coordinates to (NumPy) arrays

Shapely provides an array interface to have easy access to the coordinates as, for example, NumPy arrays ([manual section](#)).

A small example:

```
>>> line = LineString([(0, 0), (1, 1), (2, 2)])
>>> import numpy as np
>>> np.asarray(line)
array([[0., 0.],
       [1., 1.],
       [2., 2.]])
```

In addition, there are also the explicit `array_interface()` method and `ctypes` attribute to get access to the coordinates as array data:

```
>>> line.ctypes
<shapely.geometry.linestring.c_double_Array_6 at 0x7f75261eb740>
>>> line.array_interface()
{'version': 3,
 'typestr': '<f8',
 'data': <shapely.geometry.linestring.c_double_Array_6 at 0x7f752664ae40>,
 'shape': (3, 2)}
```

This functionality is available for Point, LineString, LinearRing and MultiPoint.

For more robust interoperability with NumPy, this array interface will be removed from those geometry classes, and limited to the `coords`.

Starting with Shapely 1.8, converting a geometry object to a NumPy array directly will start raising a warning:

```
>>> np.asarray(line)
ShapelyDeprecationWarning: The array interface is deprecated and will no longer
work in Shapely 2.0. Convert the '.coords' to a NumPy array instead.
array([[0., 0.],
       [1., 1.],
       [2., 2.]])
```

**How do I update my code?** To convert a geometry to a NumPy array, you can convert the `.coords` attribute instead:

```
>>> line.coords
<shapely.coords.CoordinateSequence at 0x7f2e09e88d60>
>>> np.array(line.coords)
```

(continues on next page)

(continued from previous page)

```
array([[0., 0.],
       [1., 1.],
       [2., 2.]])
```

The `array_interface()` method and `ctypes` attribute will be removed in Shapely 2.0, but since Shapely will start requiring NumPy as a dependency, you can use NumPy or its array interface directly. Check the NumPy docs on the `ctypes` attribute or the [array interface](#) for more details.

## Creating NumPy arrays of geometry objects

Shapely geometry objects can be stored in NumPy arrays using the `object` dtype. In general, one could create such an array from a list of geometries as follows:

```
>>> from shapely.geometry import Point
>>> arr = np.array([Point(0, 0), Point(1, 1), Point(2, 2)])
>>> arr
array([<shapely.geometry.point.Point object at 0x7fb798407cd0>,
       <shapely.geometry.point.Point object at 0x7fb7982831c0>,
       <shapely.geometry.point.Point object at 0x7fb798283b80>],
      dtype=object)
```

The above works for point geometries, but because in Shapely 1.x, some geometry types are sequence-like (see above), NumPy can try to “unpack” them when creating an array. Therefore, for more robust creation of a NumPy array from a list of geometries, it’s generally recommended to do this in a two-step way (first creating an empty array and then filling it):

```
geoms = [Point(0, 0), Point(1, 1), Point(2, 2)]
arr = np.empty(len(geoms), dtype="object")
arr[:] = geoms
```

This code snippet results in the same array as the example above, and works for all geometry types and Shapely/NumPy versions.

However, starting with Shapely 1.8, the above code will show deprecation warnings that cannot be avoided (depending on the geometry type, NumPy tries to access the array interface of the objects or check if an object is iterable or has a length, and those operations are all deprecated now. The end result is still correct, but the warnings appear nonetheless). Specifically in this case, it is fine to ignore those warnings (and the only way to make them go away):

```
import warnings
from shapely.errors import ShapelyDeprecationWarning

geoms = [Point(0, 0), Point(1, 1), Point(2, 2)]
arr = np.empty(len(geoms), dtype="object")

with warnings.catch_warnings():
    warnings.filterwarnings("ignore", category=ShapelyDeprecationWarning)
    arr[:] = geoms
```

In Shapely 2.0, the geometry objects will no longer be sequence like and those deprecation warnings will be removed (and thus the `filterwarnings` will no longer be necessary), and creation of NumPy arrays will generally be more robust.

If you maintain code that depends on Shapely, and you want to have it work with multiple versions of Shapely, the above code snippet provides a context manager that can be copied into your project:

```

import contextlib
import shapely
import warnings
from distutils.version import LooseVersion

SHAPELY_GE_20 = str(shapely.__version__) >= LooseVersion("2.0")

try:
    from shapely.errors import ShapelyDeprecationWarning as shapely_warning
except ImportError:
    shapely_warning = None

if shapely_warning is not None and not SHAPELY_GE_20:
    @contextlib.contextmanager
    def ignore_shapely2_warnings():
        with warnings.catch_warnings():
            warnings.filterwarnings("ignore", category=shapely_warning)
        yield
else:
    @contextlib.contextmanager
    def ignore_shapely2_warnings():
        yield

```

This can then be used when creating NumPy arrays (be careful to *only* use it for this specific purpose, and not generally suppress those warnings):

```

geoms = [...]
arr = np.empty(len(geoms), dtype="object")
with ignore_shapely2_warnings():
    arr[:] = geoms

```

### 1.3.4 Consistent creation of empty geometries

Shapely 1.x is inconsistent in creating empty geometries between various creation methods. A small example for an empty Polygon geometry:

```

# Using an empty constructor results in a GeometryCollection
>>> from shapely.geometry import Polygon
>>> g1 = Polygon()
>>> type(g1)
<class 'shapely.geometry.polygon.Polygon'>
>>> g1.wkt
GEOMETRYCOLLECTION EMPTY

# Converting from WKT gives a correct empty polygon
>>> from shapely import wkt
>>> g2 = wkt.loads("POLYGON EMPTY")
>>> type(g2)
<class 'shapely.geometry.polygon.Polygon'>
>>> g2.wkt
POLYGON EMPTY

```

Shapely 1.8 does not yet change this inconsistent behaviour, but starting with Shapely 2.0, the different methods will always consistently give an empty geometry object of the correct type, instead of using an empty `GeometryCollection` as “generic” empty geometry object.

**How do I update my code?** Those cases that will change don’t raise a warning, but you will need to update your code if you rely on the fact that empty geometry objects are of the `GeometryCollection` type. Use the `.is_empty` attribute for robustly checking if a geometry object is an empty geometry.

In addition, the WKB serialization methods will start supporting empty Points (using `"POINT (NaN NaN)"` to represent an empty point).

### 1.3.5 Other deprecated functionality

There are some other various functions and methods deprecated in Shapely 1.8 as well:

- The adapters to create geometry-like proxy objects with coordinates stored outside Shapely geometries are deprecated and will be removed in Shapely 2.0 (e.g. created using `asShape()`). They have little to no benefit compared to the normal geometry classes, as thus you can convert to your data to a normal geometry object instead. Use the `shape()` function instead to convert a GeoJSON-like dict to a Shapely geometry.
- The `empty()` method on a geometry object is deprecated.
- The `shapely.ops.cascaded_union` function is deprecated. Use `shapely.ops.unary_union` instead, which internally already uses a cascaded union operation for better performance.
